ABSTRACT. Bershadsky, Cecotti, Ooguri and Vafa constructed a real valued invariant for Calabi–Yau manifolds, which is now called the BCOV invariant. The BCOV invariant is conjecturally related to the Gromov–Witten theory via mirror symmetry. Based upon previous work of the second author, we prove the conjecture that birational Calabi–Yau manifolds have the same BCOV invariant. We also extend the construction of the BCOV invariant to Calabi–Yau varieties with Kawamata log terminal singularities, and prove its birational invariance for Calabi–Yau varieties with canonical singularities. We provide an interpretation of our construction using the theory of motivic integration.

0. Introduction

0.1. Background: mirror symmetry. BCOV torsion, introduced by Bershadsky, Cecotti, Ooguri, and Vafa in the outstanding papers [8, 9], is a real valued invariant for Calabi–Yau manifolds equipped with Ricci-flat metrics [59]. More precisely, let $X$ be a Calabi–Yau manifold, i.e., a compact Kähler manifold with trivial canonical bundle, and let $\omega$ be a Ricci-flat Kähler metric, the BCOV torsion of $(X, \omega)$ is the weighted product

\begin{equation}
\mathcal{T}_{\text{BCOV}}(X, \omega) := \prod_{p=1}^{\dim X} \mathcal{T}_p^{(-1)^p p},
\end{equation}

Key words and phrases. Analytic torsion, Calabi–Yau manifolds, motivic integration, mirror symmetry.
where $T_p$ is the analytic torsion, introduced by Ray–Singer [52], of the $p$-th exterior power of the holomorphic cotangent bundle $\bigwedge^p(T^*X)$ equipped with the induced metric.

The motivation of Bershadsky–Cecotti–Ooguri–Vafa [8, 9] comes from mirror symmetry. String theory predicts that for a family of Calabi–Yau manifolds, there is another family of Calabi–Yau manifolds with maximal degeneration, called the mirror family, such that the symplectic geometry (e.g. Gromov–Witten invariants) of the first family, called the A-model, is “equivalent” to the complex geometry (e.g. variation of Hodge structures) of the mirror family, called the B-model. Candelas–de la Ossa–Green–Parkes [18] conjectured a precise relation between the potential ($J$-function) of the genus zero Gromov–Witten invariants of quintic threefolds (A-model) and the potential ($I$-function) of the Yukawa coupling for the quintic mirror family (B-model). Such a relation is expected to hold in general for mirror Calabi–Yau families (see [50]) and gives surprising predictions in enumerative geometry. This genus zero mirror symmetry conjecture was proved by Givental [38, 39] and Lian–Liu–Yau [46] for a large class of examples including the original case of quintic threefolds. Bershadsky–Cecotti–Ooguri–Vafa [8, 9] computed certain invariants on the B-model that conjecturally correspond to higher genus Gromov–Witten invariants. This allows them to put forth conjectural formulas for all genus Gromov–Witten invariants of quintic threefolds. The genus one part of this conjecture was proved by Zinger [63, 64] in the broader setting of Calabi–Yau hypersurfaces in projective spaces. A lot of progress has been made recently on the study of Gromov–Witten invariants of genus $\geq 2$ (see [24, 23, 40, 41, 22, 21, 20, 25] and references therein). Despite the recent increasing interest on A-model invariants in genus $\geq 2$, the research on B-model invariant is currently focused on the genus one theory and the particular case of Bershadsky–Cecotti–Ooguri–Vafa’s B-model invariant corresponding to the genus one Gromov–Witten invariant is the aforementioned BCOV torsion (0.1).

The central object in this paper is the following normalization of the BCOV torsion, called the BCOV invariant. Let $X$ be an $n$-dimensional Calabi–Yau manifold equipped with a Ricci-flat metric of Kähler form $\omega$, its BCOV invariant [34, 32] is defined by

\begin{equation}
T(X) := T_{BCOV}(X, \omega) \left( \prod_{k=1}^{n} \text{covol}_{L^2}(H^k(X, \mathbb{Z}), \omega)^{(-1)^k k} \right) \left( (2\pi)^{-n} \int_{X} \omega^{n} \right)^{\chi(X)/12},
\end{equation}

where $\chi(X)$ is the topological Euler characteristic of $X$, and $\text{covol}_{L^2}(H^k(X, \mathbb{Z}))$ is the covolume of the lattice $\text{Im}(H^k(X, \mathbb{Z}) \rightarrow H^k(X, \mathbb{R}))$ with respect to the $L^2$-metric induced by $\omega$. The virtue of the BCOV invariant is that it depends only on the complex structure, but not on the Kähler metric. Fang–Lu–Yoshikawa [34] constructed the BCOV invariant for strict Calabi–Yau threefolds and studied its asymptotic behavior along degenerations. Their work confirmed the conjectural formula of Bershadsky–Cecotti–Ooguri–Vafa [8, 9] for the BCOV invariant near the large complex structure limit of the quintic mirror family (see [34, Conjecture 1.2 (B)]). Eriksson–Freixas i Montplet–Mourougane [32] generalized the construction as well as the asymptotic study of the BCOV invariant to Calabi–Yau manifolds of arbitrary dimension. They proved in [31] the conjectured formula for the BCOV invariant near the large complex
structure limit of the mirror family of Calabi–Yau hypersurfaces, and showed the compatibility with Zinger’s result on the A-model [63, 64], thus completing the genus one mirror symmetry conjecture of Bershadsky–Cecotti–Ooguri–Vafa [8, 9] in this case.

Throughout this paper, for an \( n \)-dimensional Calabi–Yau manifold \( X \), we will use the following “normalized logarithmic BCOV invariant”:

\[
\tau(X) = \log T(X) + \frac{\log(2\pi)}{2} \sum_{k=0}^{2n} (-1)^k k(k - n) b_k(X),
\]

where \( b_k(X) \) is the \( k \)-th Betti number of \( X \). This normalization comes from [61, (0.13)].

0.2. Birational invariance conjecture. As two birationally isomorphic Calabi–Yau varieties share the same mirror, their BCOV invariants should coincide. This leads to the following conjecture.

Conjecture 0.1. For birational Calabi–Yau manifolds \( X \) and \( X' \), we have \( \tau(X) = \tau(X') \).

In view of (0.3), Conjecture 0.1 is equivalent to say that \( T(X) = T(X') \), since birational Calabi–Yau manifolds have the same Betti numbers, by Batyrev [5].

Conjecture 0.1 was proposed in dimension 3 by Yoshikawa [60, Conjecture 2.1], and in arbitrary dimension by Eriksson–Freixas i Montplet–Mourougane [32, Conjecture B]. Fang–Lu–Yoshikawa [34, Conjecture 4.17] stated a weaker form of this conjecture.

Since the BCOV invariant can be thought as a “secondary” analogue of variation of Hodge structures associated with deformations of Calabi–Yau manifolds, Conjecture 0.1 is a “secondary” analogue of the theorem of Batyrev [5] and Kontsevich [45] that birational Calabi–Yau manifolds have the same Hodge numbers.

Several results were obtained towards Conjecture 0.1:

- Maillot and Rössler [49, Theorem 1.1] showed that for two smooth projective Calabi–Yau threefolds \( X, X' \) defined over a subfield \( K \) of \( \mathbb{C} \) such that \( X_K \) and \( X'_K \) are birational, then for any fixed finite set \( T \) of complex embeddings of \( K \), there exist \( n \in \mathbb{N}_{>0} \) and \( \alpha \in K^\times \), such that

\[
\tau(X'_\sigma) - \tau(X_\sigma) = \frac{1}{n} \log |\sigma(\alpha)| \quad \text{for any } \sigma \in T,
\]

where \( X_\sigma := X \otimes_{K,\sigma} \mathbb{C} \). Maillot and Rössler also proved the same result under the strictly more general hypothesis that \( X_K \) and \( X'_K \) are derived equivalent\(^1\).

- Zhang [62, Corollary 0.5] proved Conjecture 0.1 for Atiyah flops of \((-1, -1)\)-curves in Calabi–Yau threefolds.

0.3. Main results. In this paper, we confirm Conjecture 0.1.

Theorem A. Let \( X \) and \( X' \) be projective Calabi–Yau manifolds. If \( X \) and \( X' \) are birationally isomorphic, then \( \tau(X) = \tau(X') \).

\(^1\)i.e., their bounded derived categories of coherent sheaves are equivalent as \( \mathbb{C} \)-linear triangulated categories. Note that the derived equivalence of birational Calabi–Yau threefolds was proved by Bridgeland [15, Theorem 1.1], and there are derived equivalent Calabi–Yau threefolds that are not birationally equivalent [14], [27], [56].
The BCOV invariants can be extended to projective manifolds with torsion canonical bundle (or equivalently, with vanishing first Chern class by [7]), see [61]. Theorem A still holds in this more general case. In fact, we can prove the birational invariance in a much broader setting involving singular varieties.

We call a normal projective complex variety $X$ a canonical (resp. KLT) Calabi–Yau variety, if it has canonical (resp. Kawamata log terminal) singularities (cf. [44] or Definition 6.1) and $K_X \sim_Q 0$, where $\sim_Q$ is the linear equivalence relation for $\mathbb{Q}$-Cartier divisors. We will propose a natural definition of the BCOV invariant for KLT Calabi–Yau varieties (see Definition 6.9), which we still denote by $\tau$. It coincides with the usual one in the smooth case. Theorem A admits the following extension:

**Theorem B.** Let $X$ and $X'$ be canonical Calabi–Yau varieties. If $X$ and $X'$ are birationally isomorphic, then $\tau(X) = \tau(X')$.

A resolution of singularities $f : \tilde{X} \to X$ is called crepant if the relative canonical divisor $K_{\tilde{X}/X}$ is trivial. By Theorem B, the BCOV invariant of a canonical Calabi–Yau variety equals to the BCOV invariant of any crepant resolution. Note that neither the existence nor the uniqueness of crepant resolution is guaranteed. Bridgeland–King–Reid [16] proved its existence in dimension 3 for Gorenstein quotient singularities.

It is worth mentioning that in the recent work [28], Dai and Yoshikawa constructed examples showing that certain analytically defined BCOV invariants for orbifolds is not a birational invariant already in dimension 2. The orbifold surfaces in their examples have singular points worse than canonical (i.e. du Val) singularities, hence compatible with our Theorem B. Nevertheless, quotient singularities are KLT and it is highly interesting to compare our extended definition and the analytic definition for Calabi–Yau orbifolds; see Remark 6.10.

The curvature formula is of fundamental importance in the theory of BCOV invariants. We refer the readers to [34, Theorem 4.9], [32, Proposition 5.10] and [61, Theorem 0.4] for the precise formulation in the smooth case. We have the following curvature formula for the BCOV invariant of locally trivial deformation families (in the sense of Flennor–Kosarew [35], cf. Definition 6.11) of KLT Calabi–Yau varieties.

**Theorem C.** Let $S$ be a complex manifold. Let $\pi : \mathcal{X} \to S$ be a flat family of normal projective KLT Calabi–Yau varieties. Let $X_s = \pi^{-1}(s)$ for $s \in S$. Assume that $\pi$ is locally trivial. Then the following function is $C^\infty$,

\[ \tau(\mathcal{X}/S) : S \to \mathbb{R} \]

\[ s \mapsto \tau(X_s) \]  

Moreover, we have the following identity of $(1,1)$-forms on $S$,

\[ \frac{\partial \bar{\partial}}{2\pi i} \tau(\mathcal{X}/S) = \omega_{\text{Hdg},\mathcal{X}/S} - \frac{\chi(X)}{12} \omega_{\text{WP},\mathcal{X}/S} \]  

where $\chi(X)$ is the stringy Euler characteristic of $X_s$ (cf. Definition 6.8), $\omega_{\text{Hdg},\mathcal{X}/S}$ is the Hodge form of the family $\mathcal{X}/S$ (cf. Definition 6.14) and $\omega_{\text{WP},\mathcal{X}/S}$ is the Weil–Petersson form of the family $\mathcal{X}/S$ (cf. Definition 6.16).

It is still in active research to lay a rigorous foundation of a mathematical theory of B-model invariants in genus $\geq 2$. Once such a theory is built, its birational invariance
will be of great importance. We hope that our results on genus one can serve as the first step towards the big picture.

0.4. Overview of proof. To highlight the key ideas, we only explain the proof of Theorem A here. The proof contains three main ingredients.

a) BCOV invariant for pairs. The BCOV invariant for Calabi–Yau manifolds was extended by Zhang [61] to all pairs \((X, \gamma)\) with \(X\) a compact Kähler manifold and \(\gamma\) a meromorphic canonical form on \(X\) such that \(\text{div}(\gamma)\) is of simple normal crossing support and without component of multiplicity \(-1\).

We denote \(\text{div}(\gamma) = D = m_1 D_1 + \cdots + m_l D_l\) and \(D_J = \bigcap_{j \in J} D_j\) for \(J \subseteq \{1, \ldots, l\}\).

The BCOV invariant of \((X, \gamma)\) is defined by

\[
\tau(X, \gamma) = \sum_{J \subseteq \{1, \ldots, l\}} \left( \prod_{i \in J} \frac{-m_j}{m_j + 1} \right) \tau_{\text{BCOV}}(D_J, \omega) + \text{correction terms},
\]

where \(\omega\) is a Kähler form on \(X\), \(\tau_{\text{BCOV}}(D_J, \omega)\) is the (logarithmic) BCOV torsion of \((D_J, \omega|_{D_J})\) (see Definition 1.3), and the correction terms are given by Bott–Chern forms, making \(\tau(X, \gamma)\) independent of \(\omega\) (see Definition 3.2).

b) Blow-up formula. Zhang [61] worked out the precise behavior of the extended BCOV invariant \((0.7)\) under a blow-up (see Theorem 3.6). The formula of Zhang expresses the change of the BCOV invariant under a blow-up in terms of the BCOV invariant of projective spaces endowed with some canonical form, together with certain topological data. The work of Zhang is based on

- deformation to the normal cone of Baum–Fulton–MacPherson [6, §1.5];
- the immersion formula for Quillen metrics due to Bismut–Lebeau [13];
- the submersion formula for Quillen metrics due to Berthomieu–Bismut [10];
- the blow-up formula for Quillen metrics established by Bismut [11];
- the relation between the holomorphic torsion and the de Rham torsion established by Bismut [12].

c) Birational BCOV. To confirm Conjecture 0.1, by the weak factorization theorem of Abramovich, Karu, Matsuki and Włodarczyk [1, 57], it suffices to normalize the BCOV invariant \(\tau(X, \gamma)\) in \((0.7)\) in such a way that the normalized BCOV invariant does not change under blow-ups. The normalization in this paper is a linear combination of the Betti numbers of the strata \(\{D_J\}_{J \subseteq \{1, \ldots, l\}}\).

0.5. BCOV invariants and motivic integration. It might seem mysterious that the weighted sum in \((0.7)\) happens to be the right object to study, which eventually allows us to prove the birational invariance of the BCOV invariant. One conceptual progress made in this paper is an explanation of the construction of \(\tau(X, \gamma)\) (see \((0.7)\)) using Kontsevich’s motivic integration [45].

Let \((X, \gamma)\) be as in a). We temporarily assume that \(X\) is projective and \(D = \text{div}(\gamma)\) is effective. Let \(Z(X, \mathcal{I}_D; \mathbb{L}^{-1})\) be the motivic Igusa zeta function (see §4.1) associated with \((X, D)\), evaluated at \(\mathbb{L}^{-1}\). Its Hodge realization can be computed as follows:

\[
H^\bullet(Z(X, \mathcal{I}_D; \mathbb{L}^{-1})) = \sum_{J \subseteq \{1, \ldots, l\}} \mathbb{L}^{\mid J \mid - n} \left( \prod_{j \in J} \frac{1 - \mathbb{L}^{m_j}}{\mathbb{L}^{m_j+1} - 1} \right) H^\bullet(D_J).
\]

where \( L \) on the right hand side is understood as the operator of tensoring with the Lefschetz Hodge structure \( Z(-1) \). The following observation is crucial,

\[
H^\bullet\left(Z\left(X,\mathcal{I}_D;\mathbb{L}^{-1}\right)\right)_{|L=1} = \sum_{J \subseteq \{1, \ldots, l\}} \prod_{i \in J} \frac{-m_j}{m_j + 1} H^\bullet(D_J),
\]

where the coefficients are exactly the same as in (0.7). Using (0.9), we will show in §4 that the BCOV invariant \( \tau(X, \gamma) \) is essentially the Quillen metric on

\[
\bigotimes_k \left( \det H^k\left(Z\left(X,\mathcal{I}_D;\mathbb{L}^{-1}\right)\right) \right)^{(-1)^kk}.
\]

By the change of variables formula in motivic integration (cf. Theorem 4.2), the virtual Hodge structure \( H^\bullet\left(Z\left(X,\mathcal{I}_D;\mathbb{L}^{-1}\right)\right) \) in (0.8) is a birational invariant. Hence the virtual determinant line in (0.10) is also a birational invariant. This partially explains the reason why \( \tau(X, \gamma) \) is almost a birational invariant.

This paper is organized as follows.

In §1, we give a reminder on the Quillen metric and the BCOV torsion. A discussion on simple normal crossing divisors is also included.

In §2, we develop some basic properties of the so-called localizable and log-type invariants, which will appear repeatedly throughout the paper.

In §3, we recall the construction of \( \tau(X, \gamma) \) and collect several fundamental properties of the BCOV invariant.

In §4, we explain the construction of \( \tau(X, \gamma) \) using motivic integration.

In §5, we construct a birational BCOV invariant.

In §6, we extend the BCOV invariant to the singular cases and prove Theorem C.

In §7, we prove Theorem A and Theorem B.

Convection: When we write a divisor \( D = \sum_{j=1}^l m_j D_j \), we implicitly assume that the \( D_j \)’s are distinct prime divisors. For a complex manifold \( X \) and a complex submanifold \( Y \), we denote by \( \text{Bl}_Y X \) the blow-up of \( X \) along \( Y \).

Acknowledgement: We are indebted to Professor Ken-Ichi Yoshikawa for his guidance throughout the project. We would like to thank Professor Xianzhe Dai, Professor Dennis Eriksson, Professor Gerard Freixas i Montplet, Professor Chen Jiang, Professor Xiaonan Ma, and Professor Vincent Maillot for helpful discussions.

1. Preliminaries

1.1. Quillen metric and topological torsion. Let \( X \) be a compact Kähler manifold of dimension \( n \). For any holomorphic vector bundle \( E \) over \( X \), its determinant line of
motivic integration and the birational invariance of bcov 7

\[ \lambda(E) = \det H^\bullet(X, E) := \bigotimes_{q=0}^{n} (\det H^q(X, E))^{(-1)^q}. \]

For any Kähler metric on \( X \) and any Hermitian metric on \( E \), one can define the so-called Quillen metric \[51\] on the determinant line \( \lambda(E) \), see \[13, Definition 1.10\].

For \( p = 0, \ldots, n \), set

\[ \lambda_p(X) = \lambda\left(\bigwedge^p (T^*X)\right) = \bigotimes_{q=0}^{n} \left( \det H^{p,q}(X) \right)^{(-1)^q}. \]

Set

\[ \eta(X) = \det H^*_\text{dR}(X) := \bigotimes_{k=0}^{2n} \left( \det H^k_{\text{dR}}(X) \right)^{(-1)^k}. \]

By the Hodge decomposition

\[ H^k_{\text{dR}}(X) = \bigoplus_{p+q=k} H^{p,q}(X), \quad \text{for any} \quad 0 \leq k \leq n, \]

we have

\[ \eta(X) = \bigotimes_{p=0}^{n} \left( \lambda_p(X) \right)^{(-1)^p}. \]

We fix a square root of \( i \). This choice will be irrelevant. We identify the de Rham cohomology \( H^k_{\text{dR}}(X) \) with the singular cohomology \( H^k_{\text{Sing}}(X, \mathbb{C}) \) as follows,

\[ H^k_{\text{dR}}(X) \to H^k_{\text{Sing}}(X, \mathbb{C}) \]

\[ [\alpha] \mapsto [a \mapsto (2\pi i)^{-k/2} \int_a \alpha], \]

where \( \alpha \) is a closed \( k \)-form and \( a \) is a \( k \)-chain in \( X \). The identification (1.6) endows \( H^k_{\text{dR}}(X) \) with an integral structure. Let \( \epsilon_X \) be a generator of the induced integral structure on \( \eta(X) \). More precisely, for \( k = 0, \ldots, 2n \), let

\[ \sigma_{k,1}, \ldots, \sigma_{k,2n} \in H^k_{\text{Sing}}(X, \mathbb{Z})_{tf} \]

be a \( \mathbb{Z} \)-basis of the quotient of \( H^k_{\text{Sing}}(X, \mathbb{Z}) \) modulo its subgroup of torsion elements. Then \( \sigma_{k,1}, \ldots, \sigma_{k,2n} \in H^k_{\text{dR}}(X) \) form a basis of \( H^k_{\text{dR}}(X) \). Set

\[ \epsilon_X = \bigotimes_{k=0}^{2n} \left( \sigma_{k,1} \wedge \cdots \wedge \sigma_{k,2n} \right)^{(-1)^k} \in \eta(X), \]

which is well-defined up to \( \pm 1 \).

Let \( \omega \) be a Kähler form on \( X \), which induces a Hermitian metric on \( \bigwedge^p (T^*X) \) for any \( p \). Let \( \| \cdot \|_{\lambda_p(X),\omega} \) be the Quillen metric on \( \lambda_p(X) \) associated with \( \omega \). Let \( \| \cdot \|_{\eta(X)} \) be the metric on \( \eta(X) \) induced by \( \| \cdot \|_{\lambda_p(X),\omega} \) via (1.5). Proceeding in the same way as in the proof of \[62, Theorem 2.1\], we can show that \( \| \cdot \|_{\eta(X)} \) is independent of \( \omega \).
**Definition 1.1.** We define the *topological torsion* of $X$ as
\begin{equation}
\tau_{\text{top}}(X) = \log \|\epsilon_X\|_{\eta(X)}.
\end{equation}

The identification (1.6) allows us to have the following vanishing result.

**Proposition 1.2** ([61, Proposition 1.24]). *For any compact Kähler manifold* $X$, *we have*
\begin{equation}
\tau_{\text{top}}(X) = 0.
\end{equation}

**1.2. BCOV torsion.** Keep the same setting of §1.1. Following [9, §5.8], we consider the weighted product of determinant lines $\lambda_p(X)$ defined in (1.2).
\begin{equation}
\lambda(X) = \prod_{0 \leq p, q \leq n} \left( \det H^{p,q}(X) \right)^{(-1)^{p+q}} = \prod_{p=1}^{n} \left( \lambda_p(X) \right)^{(-1)^p}.
\end{equation}

Set
\begin{equation}
\lambda_{\text{dR}}(X) = \prod_{k=1}^{2n} \left( \det H^k_{\text{dR}}(X) \right)^{(-1)^k}.
\end{equation}

By the Hodge decomposition (1.4), we have
\begin{equation}
\lambda_{\text{dR}}(X) = \lambda(X) \otimes \bar{\lambda}(X).
\end{equation}

The identity (1.13) appeared in Kato [42] and was first applied to this setting in [32].

Let $\|\cdot\|_{\lambda(X),\omega}$ be the metric on $\lambda(X)$ induced by $\|\cdot\|_{\lambda_p(X),\omega}$ via (1.11). Let $\|\cdot\|_{\lambda_{\text{dR}}(X),\omega}$ be the metric on $\lambda_{\text{dR}}(X)$ induced by $\|\cdot\|_{\lambda(X),\omega}$ via (1.13). Let $\sigma_X$ be the integral generator of $\lambda_{\text{dR}}(X)$ defined as follows, using the $\mathbb{Z}$-basis of $H^*_{\text{Sing}}(X,\mathbb{Z})$ in (1.7),
\begin{equation}
\sigma_X = \prod_{k=1}^{2n} \left( \sigma_{k,1} \wedge \cdots \wedge \sigma_{k,b_k} \right)^{(-1)^k}.
\end{equation}

**Definition 1.3.** We define the *BCOV torsion* of $(X,\omega)$ as
\begin{equation}
\tau_{\text{BCOV}}(X,\omega) = \log \|\sigma_X\|_{\lambda_{\text{dR}}(X),\omega}.
\end{equation}

In the case where $X$ is a Calabi–Yau manifold equipped with a Ricci-flat metric $\omega$, this invariant $\tau_{\text{BCOV}}(X,\omega)$ is precisely the logarithm of the product of the first two factors on the right hand side of (0.2).

**1.3. Divisor with simple normal crossing support.** For $I \subseteq \{1, \ldots, n\}$, set
\begin{equation}
\mathbb{C}^n_I = \left\{ (z_1, \cdots, z_n) \in \mathbb{C}^n : \ z_i = 0 \text{ for } i \in I \right\} \subseteq \mathbb{C}^n.
\end{equation}

Let $X$ be a complex manifold of dimension $n$. Let $Y_1, \cdots, Y_l \subseteq X$ be closed complex submanifolds.

**Definition 1.4.** We say that $Y_1, \cdots, Y_l$ transversally intersect if for any $x \in X$, there exists a holomorphic local chart $\mathbb{C}^n \supseteq U \xrightarrow{\varphi} X$ such that
- $0 \in U$ and $\varphi(0) = x$;
- for each $k = 1, \cdots, l$, either $\varphi^{-1}(Y_k) = \emptyset$, or $\varphi^{-1}(Y_k) = U \cap \mathbb{C}^n_I$ for certain $I_k \subseteq \{1, \cdots, n\}$. 
Let $D$ be a divisor on $X$. We denote

$$D = \sum_{j=1}^{l} m_j D_j,$$

where $m_j \in \mathbb{Z} \setminus \{0\}$ and $D_1, \cdots, D_l \subseteq X$ are mutually distinct prime divisors.

**Definition 1.5.** We say that $D$ is a divisor with simple normal crossing support if $D_1, \cdots, D_l$ are smooth and transversally intersect.

Now we assume that $D$ is a divisor with simple normal crossing support. Let $L$ be the holomorphic line bundle $\mathcal{O}_X(D)$. Let $\gamma \in \mathcal{M}(X, L)$ such that $\text{div}(\gamma) = D$. Let $\gamma^{-1} \in \mathcal{M}(X, L^{-1})$ be the inverse of $\gamma$.

For $k \in \mathbb{N}$, we denote by $(T^*\, X \oplus T^{-1}_X)^{\otimes k}$ the $k$-th tensor power of $T^*\, X \oplus T^{-1}_X$. Set

$$E_k^\pm = (T^*\, X \oplus T^{-1}_X)^{\otimes k} \otimes L^\pm_1.$$

In particular, we have $E_0^\pm = L^\pm$. Let $\nabla E_k^\pm$ be a connection on $E_k^\pm$.

Let $L_j$ be the normal line bundle of $D_j \hookrightarrow X$.

**Definition 1.6.** We define $\text{Res}_{D_j}(\gamma) \in \mathcal{M}(D_j, L \otimes L_j^{-m_j})$ as follows,

$$\text{Res}_{D_j}(\gamma) = \begin{cases} \frac{1}{m_j!} \left( \nabla E_{m_j-1}^+ \cdots \nabla E_0^+ \gamma \right) \big|_{D_j} & \text{if } m_j > 0, \\ \frac{1}{m_j!} \left( \nabla E_{m_j-1}^- \cdots \nabla E_0^- \gamma^{-1} \right) \big|_{D_j} & \text{if } m_j < 0. \end{cases}$$

We can show that $\text{Res}_{D_j}(\gamma)$ is independent of $(\nabla E_k^\pm)_{k \in \mathbb{N}}$.

Let $\mathbb{C}^n \supseteq U \xrightarrow{\varphi} X$ be a local chart as in Definition 1.4. Assume that

$$\gamma \big|_{\varphi(U)} = s\varphi^*(z_1^{m_1} \cdots z_n^{m_n}),$$

where $0 \leq r \leq n$ and $s \in H^0(\varphi(U), L)$ is nowhere vanishing. For $j = 1, \cdots, r$, we have

$$\text{Res}_{D_j}(\gamma) \big|_{D_j \cap \varphi(U)} = s\varphi^*(z_1^{m_1} \cdots z_j^{m_j-1} \cdot z_{j+1}^{m_{j+1}} \cdots z_r^{m_r} (dz_j)^{m_j}).$$

Note that

$$\text{div}(\text{Res}_{D_1}(\gamma)) = \sum_{j=2}^{l} m_j (D_1 \cap D_j).$$

The following identity holds in $\mathcal{M}(D_1 \cap D_2, L \otimes L_1^{-m_1} \otimes L_2^{-m_2})$,

$$\text{Res}_{D_1 \cap D_2}(\text{Res}_{D_1}(\gamma)) = \text{Res}_{D_1 \cap D_2}(\text{Res}_{D_2}(\gamma)).$$

In other words, the order of taking $\text{Res}(\cdot)$ does not matter.
2. Localizable invariants

2.1. Definitions and examples.

Definition 2.1. Let $\text{Käh}$ be the category of compact Kähler manifolds. Let $\phi : \text{Käh} \to \mathbb{R}$ be a function that depends only on the isomorphism classes of compact Kähler manifolds.

- $\phi$ is called a localizable invariant if for any $X, X' \in \text{Käh}$, and closed complex submanifolds $Y \subseteq X, Y' \subseteq X'$ such that $Y \simeq Y'$ and $N_{Y/X} \simeq N_{Y'/X'}$, we have
  \begin{equation}
  \phi(\text{Bl}_{Y} X) - \phi(X) = \phi(\text{Bl}_{Y'} X') - \phi(X') .
  \end{equation}

- $\phi$ is called log-type if for any $X \in \text{Käh}$ and $V$ a holomorphic vector bundle of rank $r$ over $X$, we have
  \begin{equation}
  \phi(\mathbb{P}(V)) = \chi(\mathbb{CP}^{r-1})\phi(X) + \chi(X)\phi(\mathbb{CP}^{r-1}) .
  \end{equation}

- $\phi$ is called additive if for any $X \in \text{Käh}$ and $Y \subseteq X$ a closed complex submanifold, we have
  \begin{equation}
  \phi(\text{Bl}_{Y} X) - \phi(X) = \phi(\mathbb{P}(N_{Y/X})) - \phi(Y) .
  \end{equation}

An additive invariant is clearly localizable. A linear combination of localizable (resp. log-type, additive) invariants is again localizable (resp. log-type, additive).

Let us give several examples of such invariants that will play important roles later.

Examples 2.2. Let $X$ be a compact Kähler manifold.

- For any $k \in \mathbb{N}$, the $k$-th Betti number $b_{k}(X)$ is an additive invariant. Let
  \begin{equation}
  P_{t}(X) = \sum_{k=0}^{2\text{dim } X} b_{k}(X)t^{k}
  \end{equation}
  be the Poincaré polynomial. For any $t \in \mathbb{R}$, $P_{t}(X)$ is an additive invariant. In particular, the topological Euler characteristic
  \begin{equation}
  \chi(X) = P_{-1}(X)
  \end{equation}
  is additive.

- The invariant
  \begin{equation}
  \chi'(X) = \frac{d}{dt}P_{t}(X)\Big|_{t=-1} = \text{dim}(X)\chi(X)
  \end{equation}
  is log-type and additive. To show that $\chi'(X)$ is log-type (i.e., identity (2.2)), we take the derivative of the identity $P_{t}(\mathbb{P}(V)) = P_{t}(X)P_{t}(\mathbb{CP}^{r-1})$.

- The invariant
  \begin{equation}
  \chi''(X) = \frac{d^{2}}{dt^{2}}P_{t}(X)\Big|_{t=-1} - \text{dim}(X)^{2}\chi(X) = P_{t}(X)\frac{d^{2}}{dt^{2}}\log P_{t}(X)\Big|_{t=-1}
  \end{equation}
  is log-type and localizable (but not additive). To show that $\chi''(X)$ is log-type (i.e., identity (2.2)), we take the second derivative of the logarithm of the identity $P_{t}(\mathbb{P}(V)) = P_{t}(X)P_{t}(\mathbb{CP}^{r-1})$.

\footnote{The terminology refers to the fact that if $\chi(X) \neq 0$, then $\frac{\phi(\mathbb{P}(V))}{\chi(\mathbb{P}(V))} = \frac{\phi(X)}{\chi(X)} + \frac{\phi(\mathbb{CP}^{r-1})}{\chi(\mathbb{CP}^{r-1})}$.}
2.2. Localizable invariant for pairs. Let $d$ be a non-zero integer.

**Definition 2.3.** For a compact Kähler manifold $X$ and a divisor

\[(2.8) \quad D = \sum_{j=1}^{l} m_j D_j \]

on $X$, we say that $(X, D)$ satisfies condition $(\ast_d)$ if $D$ is of simple normal crossing support and $m_j \neq -d$ for all $j$.

We will always use the following notation. For $J \subseteq \{1, \ldots, l\}$, set

\[(2.9) \quad w_d^J = \prod_{j \in J} \frac{-m_j}{m_j + d}, \quad D_J = X \cap \bigcap_{j \in J} D_j. \]

In particular, $w_d^\emptyset = 1$ and $D_\emptyset = X$.

**Definition 2.4.** Let $\phi$ be a localizable invariant. Let $d \in \mathbb{Z}\setminus\{0\}$. For $(X, D)$ satisfying the condition $(\ast_d)$, we define

\[(2.10) \quad \phi_d(X, D) = \sum_{J \subseteq \{1, \ldots, l\}} w_d^J \phi(D_J). \]

If there is a meromorphic section $\gamma$ of a holomorphic line bundle over $X$ such that $\text{div}(\gamma) = D$, we define $\phi_d(X, \gamma) = \phi_d(X, D)$.

Let $[\xi_0 : \cdots : \xi_n] \in \mathbb{C}P^n$ be homogenous coordinates. For $j = 0, \cdots, n$, we denote $H_j = \{\xi_j = 0\} \subseteq \mathbb{C}P^n$. For $m_0, \ldots, m_n \in \mathbb{Z}$, we denote

\[(2.11) \quad D_{m_0, \ldots, m_n} = \sum_{j=0}^{n} m_j H_j. \]

Recall that $\chi$ is the topological Euler characteristic. By Definition 2.4, $\chi_d(\cdot, \cdot)$ is well-defined.

**Lemma 2.5.** For $d \in \mathbb{Z}\setminus\{0\}$ and $m_0, \ldots, m_n \in \mathbb{Z}\setminus\{-d\}$, we have

\[(2.12) \quad \chi_d(\mathbb{C}P^n, D_{m_0, \ldots, m_n}) = \left( \prod_{j=0}^{n} (m_j + d) \right)^{-1} \sum_{j=0}^{n} (m_j + d). \]

In particular, $\chi_d(\mathbb{C}P^n, D_{m_0, \ldots, m_n})$ vanishes if and only if $D_{m_0, \ldots, m_n}$ is a $d$-canonical divisor.

**Proof.** Let $w_d^J$ be as in (2.9). By Definition 2.4, we have

\[(2.13) \quad \chi_d(\mathbb{C}P^n, D_{m_0, \ldots, m_n}) = \sum_{J \subseteq \{0, \ldots, n\}} w_d^J (n + 1 - |J|). \]

Set

\[(2.14) \quad f(t) = \prod_{j=0}^{n} \left( t - \frac{m_j}{m_j + d} \right) = \sum_{J \subseteq \{0, \ldots, n\}} w_d^J t^{n+1-|J|}. \]

By (2.13) and (2.14), we have

\[(2.15) \quad \chi_d(\mathbb{C}P^n, D_{m_0, \ldots, m_n}) = f'(1), \quad \frac{f'(1)}{f(1)} = \left. \frac{d}{dt} \log f(t) \right|_{t=1} = \sum_{j=0}^{n} \frac{m_j + d}{d}. \]
From (2.14) and (2.15), we obtain (2.12). This completes the proof. □

Let $Y$ be a compact Kähler manifold and $V$ be a holomorphic vector bundle of rank $r$ over $Y$. Set $X = \mathbb{P}(V)$. Let $\pi : X \to Y$ be the canonical projection. Let $D$ be a divisor on $X$. We assume that there exist a divisor $D_Y$ on $Y$, non-zero integers $m_1, \cdots, m_s$, and holomorphic sub-bundles $V_1, \cdots, V_s \subseteq V$ of rank $r - 1$, such that

\[(2.16)\]

\[D = \pi^* D_Y + \sum_{j=1}^{s} m_j \mathbb{P}(V_j) .\]

We further assume that $V_1, \cdots, V_s \subseteq V$ transversally intersect. In particular, $s \leq r$. We will use the convention $m_{s+1} = \cdots = m_r = 0$. For $y \in Y$, we denote $Z_y = \pi^{-1}(y)$. Set

\[(2.17)\]

\[D_{Z_y} = \sum_{j=1}^{s} m_j (\mathbb{P}(V_j) \cap Z_y) .\]

Then $(Z_y, D_{Z_y})$ is isomorphic to $(\mathbb{C}P^{r-1}, D_{m_1, \cdots, m_s})$ for any $y \in Y$. In the sequel, we omit the index $y$ in $(Z_y, D_{Z_y})$. Such a pair $(X, D)$ will be called a fibration over $(Y, D_Y)$ with fiber $(Z, D_Z)$.

**Lemma 2.6.** Assume that $D$ satisfies the condition $(\ast_d)$ in Definition 2.3. We have

\[(2.18)\]

\[\chi_d(X, D) = \chi_d(Y, D_Y) \chi_d(Z, D_Z) .\]

**Proof.** It is a straightforward computation from Definition 2.4 by using the fact that $\chi(\cdot)$ is an additive invariant and is multiplicative with respect to products of varieties. □

**Proposition 2.7.** Let $\phi$ be a log-type localizable invariant and $d \in \mathbb{Z}\setminus\{0\}$. Assume that $D$ is a $d$-canonical divisor and satisfies the condition $(\ast_d)$. We have

\[(2.19)\]

\[\phi_d(X, D) = \chi_d(Y, D_Y) \phi_d(Z, D_Z) .\]

**Proof.** By Definitions 2.1 and 2.4, we have

\[(2.20)\]

\[\phi_d(X, D) = \chi_d(Y, D_Y) \phi_d(Z, D_Z) + \phi_d(Y, D_Y) \chi_d(Z, D_Z) .\]

Since $(X, D)$ is $d$-canonical, so is $(Z, D_Z)$. By Lemma 2.5, we have

\[(2.21)\]

\[\chi_d(Z, D_Z) = 0 .\]

From (2.20) and (2.21), we obtain (2.19). This completes the proof. □

For $r \in \mathbb{N}\setminus\{0\}$ and $m_1, \cdots, m_s \in \mathbb{Z}$ with $s \leq r$, let $(\mathbb{C}P^r, D_{m_1, \cdots, m_s})$ be such that

\[(2.22)\]

\[D_{m_1, \cdots, m_s} = \sum_{j=1}^{s} m_j H_j .\]

For $r \in \mathbb{N}\setminus\{0\}$ and $m_1, \cdots, m_s \in \mathbb{Z}$ with $s \leq r$, let $(\mathbb{C}P^r, D_{d,m_1, \cdots, m_s})$ be such that

\[(2.23)\]

\[D_{d,m_1, \cdots, m_s} = -(m_1 + \cdots + m_s + rd + d)H_0 + \sum_{j=1}^{s} m_j H_j .\]

We remark that $D_{d,m_1, \cdots, m_s}$ is a $d$-canonical divisor.
Let $X$ be a compact Kähler manifold. Let

\begin{equation}
D = \sum_{j=1}^{l} m_j D_j
\end{equation}

be a divisor on $X$ with simple normal crossing support. Let $Y \subseteq X$ be a connected complex submanifold of codimension $r$ intersecting $D_1, \ldots, D_l$ transversally and

\begin{equation}
Y \subseteq D_j \quad \text{for } j = 1, \ldots, s; \quad Y \not\subseteq D_j \quad \text{for } j = s+1, \ldots, l.
\end{equation}

In particular, $s \leq r$. Set

\begin{equation}
D_Y = \sum_{j=s+1}^{l} m_j (D_j \cap Y).
\end{equation}

Let $f : X' \to X$ be the blow-up along $Y$. Let $\tilde{D}$ be the strict transformation of $D$. Let $E = f^{-1}(Y) \subseteq X$ be the exceptional divisor. Set

\begin{equation}
D' = \tilde{D} + m_e E, \quad \text{where } m_e = (r - 1)d + m_1 + \cdots + m_s.
\end{equation}

Note that if $D$ is a $d$-canonical divisor, then so is $D'$.

**Proposition 2.8.** Let $\phi$ be a log-type localizable invariant and $d \in \mathbb{Z} \setminus \{0\}$. Assume that $D$ is a $d$-canonical divisor and satisfies the condition $(\ast_d)$ in Definition 2.3. We have

\begin{align*}
\chi_d(X', D') - \chi_d(X, D) &= 0, \\
\phi_d(X', D') - \phi_d(X, D) &= \chi_d(Y, D_Y) \left( \chi_d(\mathbb{CP}^{r-1}, D_{m_1}, \ldots, m_s) \phi_d(\mathbb{CP}^1, D_d, m_s) - \phi_d(\mathbb{CP}^r, D_d, m_1, \ldots, m_s) \right).
\end{align*}

**Proof.** Denote by $1$ the trivial line bundle. Set $W = \mathbb{F}(N_{Y/X} \oplus 1)$. Let $\pi : W \to Y$ be the canonical projection. Let $\iota : Y \hookrightarrow W$ be the inclusion by the zero section of $N_{Y/X}$. Let $g : W' \to W$ be the blow-up along $\iota(Y)$. Set

\begin{equation}
D_W = \pi^*(D_Y) - (m_e + 2d) \mathbb{P}(N_{Y/X}) + \sum_{j=1}^{s} m_j \mathbb{P}(N_{Y/D_j} \oplus 1).
\end{equation}

Let $\tilde{D}_W$ be the strict transformation of $D_W$. We still use $E$ to denote the exceptional divisor of $g : W' \to W$. Set $D_{W'} = \tilde{D}_W + m_e E$. By Definition 2.4 and (2.1), we have

\begin{align*}
\chi_d(X', D') - \chi_d(X, D) &= \chi_d(W', D_{W'}) - \chi_d(W, D_W), \\
\phi_d(X', D') - \phi_d(X, D) &= \phi_d(W', D_{W'}) - \phi_d(W, D_W).
\end{align*}

Note that $(W, D_W)$ is a fibration over $(Y, D_Y)$ with fiber $(\mathbb{CP}^r, D_{d,m_1,\ldots,m_s})$, by Lemma 2.5, 2.6 and Proposition 2.7, we have

\begin{align*}
\chi_d(W, D_W) &= \chi_d(Y, D_Y) \chi_d(\mathbb{CP}^r, D_{d,m_1,\ldots,m_s}) = 0, \\
\phi_d(W, D_W) &= \chi_d(Y, D_Y) \phi_d(\mathbb{CP}^r, D_{d,m_1,\ldots,m_s}).
\end{align*}
We denote $D_E = \tilde{D}_W|_E$. Note that $W'$ is fibration over $Y$ with fiber $\text{Bl}_0\mathbb{C}P^r$, and $\text{Bl}_0\mathbb{C}P^r$ is a fibration over $\mathbb{C}P^{r-1}$ with fiber $\mathbb{C}P^1$, we can show that $(W', D_{W'})$ is fibration over $(E, D_E)$ with fiber $(\mathbb{C}P^1, D_{d_{m_0}})$. By Lemma 2.5, 2.6 and Proposition 2.7, we have

$$
\chi_d(W', D_{W'}) = \chi_d(E, D_E)\chi_d(\mathbb{C}P^1, D_{d_{m_0}}) = 0 ,
$$

$$
\phi_d(W', D_{W'}) = \chi_d(E, D_E)\phi_d(\mathbb{C}P^1, D_{d_{m_0}}) .
$$

Note that $(E, D_E)$ is fibration over $(Y, D_Y)$ with fiber $(\mathbb{C}P^{r-1}, D_{m_1, \ldots, m_s})$, by Lemma 2.6, we have

$$
\chi_d(E, D_E) = \chi_d(Y, D_Y)\chi_d(\mathbb{C}P^{r-1}, D_{m_1, \ldots, m_s}) .
$$

From (2.30)-(2.33), we obtain (2.28). This completes the proof. \hfill \Box

3. BCOV invariants for pairs

3.1. BCOV invariants. Let $X$ be a compact Kähler manifold. Let $K_X$ be the canonical bundle of $X$. Let $d \in \mathbb{Z}\setminus\{0\}$. Let $\gamma \in \mathcal{M}(X, K_X')$ be an invertible element. We denote

$$
div(\gamma) = D = \sum_{j=1}^l m_jD_j ,
$$

where $m_j \in \mathbb{Z}\setminus\{0\}$ and $D_1, \ldots, D_l \subseteq X$ are mutually distinct prime divisors.

**Definition 3.1.** We call $(X, \gamma)$ a $d$-Calabi–Yau pair if $(X, \text{div}(\gamma))$ satisfies the condition $(\star_d)$ in Definition 2.3.

Now we assume that $(X, \gamma)$ is a $d$-Calabi–Yau pair.

Let $D_J$ be as in (2.9). For any $j \in J \subseteq \{1, \ldots, l\}$, let $L_{J,j}$ be the normal line bundle of $D_J \hookrightarrow D_{J\setminus\{j\}}$. For $J \subseteq \{1, \ldots, l\}$, set

$$
K_J = K_X'|_{D_J} \otimes \bigotimes_{j \in J} L_{J,j}^{-m_j} = K_{D_j}^d \otimes \bigotimes_{j \in J} L_{J,j}^{-m_j-d} .
$$

which is a holomorphic line bundle over $D_J$. In particular, we have $K_\emptyset = K_X'$.

Recall that $\text{Res}(\cdot)$ was defined in Definition 1.6. By (1.23), there exist

$$
\left( \gamma_j \in \mathcal{M}(D_J, K_J) \right)_{\{1, \ldots, l\}}
$$

such that

$$
\gamma_\emptyset = \gamma , \quad \gamma_j = \text{Res}_{D_J}(\gamma_{J\setminus\{j\}}) \quad \text{for} \ j \in J \subseteq \{1, \ldots, l\} .
$$

Let $\omega$ be a Kähler form on $X$. Let $|\cdot|_{K_{D_J}^\omega}$ be the metric on $K_{D_J}$ induced by $\omega$. Let $|\cdot|_{L_{J,j}^\omega}$ be the metric on $L_{J,j}$ induced by $\omega$. Let $|\cdot|_{K_J^\omega}$ be the metric on $K_J$ induced by $|\cdot|_{K_{D_J}^\omega}$ and $|\cdot|_{L_{J,j}^\omega}$ via (3.2).

Let $g_{T_{D_J}}^\omega$ be the metric on $TD_J$ induced by $\omega$. Let $c_k(TD_J, g_{T_{D_J}}^\omega)$ be $k$-th Chern form of $(TD_J, g_{T_{D_J}}^\omega)$. Recall that $\gamma_j \in \mathcal{M}(D_J, K_J)$ was defined by (3.4). Let $n$ be the dimension of $X$. Let $|J|$ be the number of elements in $J$. Set

$$
a_j(\gamma, \omega) = \frac{1}{12} \int_{D_J} c_{n-|J|}(TD_J, g_{T_{D_J}}^\omega) \log |\gamma_j|_{K_J^\omega}^{2/d} .
$$
Recall that \( L_{J,j} \) is the normal line bundle of \( D_J \to D_{J \setminus \{j\}} \). We consider the short exact sequence of holomorphic vector bundles over \( D_J \),
\[
0 \to TD_J \to TD_{J \setminus \{j\}}|_{D_J} \to L_{J,j} \to 0.
\]
Let \( g_\omega^{TD_{J \setminus \{j\}}} \) be the metric on \( TD_{J \setminus \{j\}} \) induced by \( \omega \). Let
\[
\tilde{c}\left(TD_J, TD_{J \setminus \{j\}}|_{D_J}, g_\omega^{TD_{J \setminus \{j\}}}|_{D_J}\right)
\]
be the same Bott–Chern form as in [62, §1.1]. Set
\[
b_{J,j}(\omega) = \frac{1}{12} \int_{D_J} \tilde{c}\left(TD_J, TD_{J \setminus \{j\}}|_{D_J}, g_\omega^{TD_{J \setminus \{j\}}}|_{D_J}\right).
\]
Let \( w_d \) be as in (2.9). For ease of notations, we denote \( \tau_{BCOV}(D_J, \omega) = \tau_{BCOV}(D_J, \omega|_{D_J}) \).
Zhang [61, Definition 3.2] defined the following extended BCOV invariant.

**Definition 3.2.** The BCOV invariant of a \( d \)-Calabi–Yau pair \((X, \gamma)\) is defined by
\[
\tau_d(X, \gamma) = \sum_{J \subseteq \{1, \ldots, d\}} w_d^J \left( \tau_{BCOV}(D_J, \omega) - a_J(\gamma, \omega) - \sum_{j \in J} m_j + \frac{d}{d} b_{J,j}(\omega) \right).
\]
It is shown in [61, Theorem 3.1] that \( \tau_d(X, \gamma) \) is independent of \( \omega \).

### 3.2. Projective spaces of dimension 1 and 2
We identify \( \mathbb{C}P^n \) with \( \mathbb{C}^n \cup \mathbb{C}P^{n-1} \).
Let \((z_1, \ldots, z_n) \in \mathbb{C}^n\) be the affine coordinates. For \( m_1, \ldots, m_n \in \mathbb{N} \), let \( \gamma_{m_1, \ldots, m_n} \in \mathcal{M}(\mathbb{C}P^n, K_{\mathbb{C}P^n}) \) be such that
\[
\gamma_{m_1, \ldots, m_n}|_{\mathbb{C}^n} = z_1^{m_1} \cdots z_n^{m_n} (dz_1 \wedge \cdots \wedge dz_n)^d.
\]
Then \((\mathbb{C}P^n, \gamma_{m_1, \ldots, m_n})\) is a \( d \)-Calabi–Yau pair.
We denote
\[
\tau(\mathbb{C}P^n) = \tau_d(\mathbb{C}P^n, \gamma_{0, \ldots, 0}).
\]
By [61, Proposition 3.3], \( \tau(\mathbb{C}P^n) \) is well-defined, i.e., independent of \( d \).

**Theorem 3.3.** For any \( m \in \mathbb{N} \), we have
\[
\tau_d(\mathbb{C}P^1, \gamma_m) = \tau(\mathbb{C}P^1).
\]
In other words, \( \tau_d(\mathbb{C}P^1, \gamma_m) \) is independent of \( m \).

**Proof.** Let \( w = 1/z \). We have
\[
\gamma_m = z^m (dz)^d = \frac{(-1)^d}{4^m + 2d} (dw)^d.
\]
We have \( \text{div}(\gamma_m) = m\{0\} - (m + 2d)\{\infty\} \). Recall that \( \text{Res}(\cdot) \) was defined in Definition 1.6. We have
\[
\text{Res}_{\{0\}}(\gamma_m) = (dz)^{m+d}, \quad \text{Res}_{\{\infty\}}(\gamma_m) = (-1)^d (dw)^{-m-d}.
\]
Let $\omega$ be a Kähler form on $\mathbb{CP}^1$. Let $g^{TCP^1}$ (resp. $g^{T^*\mathbb{CP}^1}$) be the metric on $TCP^1$ (resp. $T^*\mathbb{CP}^1$) induced by $\omega$. Let $|dz|$ (resp. $|dw|$) be the norm of $dz$ (resp. $dw$) with respect to $g^{T^*\mathbb{CP}^1}$. Note that $\tau_{BCOV}(pt) = 0$, we have

$$
\tau_d(\mathbb{CP}^1, \gamma_m) = \tau_{BCOV}(\mathbb{CP}^1, \omega) - \frac{1}{12} \int_{\mathbb{CP}^1} c_1(TCP^1, g^{TCP^1}) \log |dz|^2 - \frac{1}{12} \frac{m}{d} \int_{\mathbb{CP}^1} c_1(TCP^1, g^{TCP^1}) \log |z|^2 + \frac{m}{12} \log |dz|_0^2 - \frac{m + 2d}{12} \log |dw|_\infty^2.
$$

(3.15)

In the sequel, we take the Fubini–Study metric on $\mathbb{CP}^1$, whose Kähler form is

$$
\omega = \frac{i dz \wedge d\overline{z}}{(1 + |z|^2)^2}.
$$

(3.16)

We have

$$
c_1(TCP^1, g^{TCP^1}) = \frac{\omega}{\pi}, \quad |dz|^2 = (1 + |z|^2)^2.
$$

(3.17)

By (3.16) and (3.17), we have

$$
\log |dz|_0^2 = \log |dw|_\infty^2 = 0, \quad \int_{\mathbb{CP}^1} c_1(TCP^1, g^{TCP^1}) \log |z|^2 = 0.
$$

(3.18)

By (3.15) and (3.18), we obtain (3.12). This completes the proof.

Theorem 3.4. For any $m_1, m_2 \in \mathbb{N}$, we have

$$
\tau_d(\mathbb{CP}^2, \gamma_{m_1, m_2}) = \tau(\mathbb{CP}^2) + \left(\frac{3}{2} - \frac{m_1}{m_1 + d} - \frac{m_2}{m_2 + d} - \frac{m_1 + m_2 + 3d}{m_1 + m_2 + 2d}\right) \tau(\mathbb{CP}^1).
$$

(3.19)

Proof. Let $[\xi_0 : \xi_1 : \xi_2]$ be homogeneous coordinates on $\mathbb{CP}^2$. Let $H_1 \subseteq \mathbb{CP}^2$ (resp. $H_2 \subseteq \mathbb{CP}^2$, $H_\infty \subseteq \mathbb{CP}^2$) be defined by $\xi_1 = 0$ (resp. $\xi_2 = 0$, $\xi_0 = 0$). Set

$$
z_1 = \xi_1/\xi_0, \quad z_2 = \xi_2/\xi_0, \quad w_0 = \xi_0/\xi_2, \quad w_1 = \xi_1/\xi_2, \quad t_0 = \xi_0/\xi_1, \quad t_2 = \xi_2/\xi_1.
$$

(3.20)

Then $(z_1, z_2)$ (resp. $(w_0, w_1)$, $(t_0, t_2)$) are affine coordinates on $\mathbb{CP}^2 \setminus H_\infty$ (resp. $\mathbb{CP}^2 \setminus H_2$, $\mathbb{CP}^2 \setminus H_1$). We have

$$
\gamma_{m_1, m_2} = z_1^{m_1} z_2^{m_2} (dz_1 \wedge dz_2)^d = \frac{w_1^{m_1}}{w_0^{m_1 + m_2 + 3d}} (dw_0 \wedge dw_1)^d = \frac{t_2^{m_2}}{t_0^{m_1 + m_2 + 3d}} (dt_2 \wedge dt_0)^d.
$$

(3.21)

We remark that $\text{div}(\gamma_{m_1, m_2}) = m_1 H_1 + m_2 H_2 - (m_1 + m_2 + 3d) H_\infty$.
Recall that $\text{Res} (\cdot)$ was defined in Definition 1.6. We have

$$\begin{align*}
\text{Res}_{H_1}(\gamma_{m_1, m_2}) &= z_2^{m_2} (dz_1)^{m_1+d} (dz_2)^d, \\
\text{Res}_{H_2}(\gamma_{m_1, m_2}) &= z_1^{m_1} (dz_2)^{m_2+d} (dz_1)^d, \\
\text{Res}_{H_\infty}(\gamma_{m_1, m_2}) &= w_1^{m_1} (dw_0)^{-m_1-m_2-2d} (dw_1)^d, \\
\text{Res}_{H_1 \cap H_2}(\text{Res}_{H_1}(\gamma_{m_1, m_2})) &= (dz_1)^{m_1+d} (dz_2)^{m_2+d}, \\
\text{Res}_{H_1 \cap H_\infty}(\text{Res}_{H_\infty}(\gamma_{m_1, m_2})) &= (dw_0)^{-m_1-m_2-2d} (dw_1)^{m_1+d}, \\
\text{Res}_{H_2 \cap H_\infty}(\text{Res}_{H_\infty}(\gamma_{m_1, m_2})) &= (dt_0)^{-m_1-m_2-2d} (dt_2)^{m_2+d}.
\end{align*}$$

(3.22)

We fix a Fubini–Study metric on $\mathbb{C}P^2$, whose Kähler form is as follows:

$$\omega = \frac{i (dz_1 \wedge d\bar{z}_1 + dz_2 \wedge d\bar{z}_2 - \bar{z}_1 z_2 dz_1 \wedge d\bar{z}_2 - z_1 \bar{z}_2 d\bar{z}_1 \wedge dz_2)}{(1 + |z_1|^2 + |z_2|^2)^2}. $$

(3.23)

We will use the notations in (3.9). With our choice of Kähler form (3.23), we have

$$a_J(\gamma_{m_1, m_2}, \omega) = b_{J,j}(\omega) = 0 \quad \text{for } |J| = 2, \quad b_{J,j}(\omega) = 0 \quad \text{for } |J| = 1. $$

(3.24)

By (3.9), (3.23), (3.24) and the fact that $\tau_{\text{BCOV}}(\text{pt}) = 0$, we have

$$\begin{align*}
\tau_d(\mathbb{C}P^2, \gamma_{m_1, m_2}) &= \tau_{\text{BCOV}}(\mathbb{C}P^2, \omega) - \frac{1}{12d} \frac{1}{12d} \int_{\mathbb{C}P^2} c_2(T\mathbb{C}P^2, g^{T\mathbb{C}P^2}) \log \left| z_1^{m_1} z_2^{m_2} (dz_1 \wedge dz_2)^d \right|^2 \\
&= \frac{m_1}{m_1 + d} \left( \tau_{\text{BCOV}}(H_1, \omega) \\
&\quad - \frac{1}{12d} \int_{H_1} c_1(TH_1, g^{TH_1}) \log \left| z_2^{m_2} (dz_1)^{m_1+d} (dz_2)^d \right|^2 \right) \\
&- \frac{m_2}{m_2 + d} \left( \tau_{\text{BCOV}}(H_2, \omega) \\
&\quad - \frac{1}{12d} \int_{H_2} c_1(TH_2, g^{TH_2}) \log \left| z_1^{m_1} (dz_2)^{m_2+d} (dz_1)^d \right|^2 \right) \\
&- \frac{m_1 + m_2 + 3d}{m_1 + m_2 + 2d} \left( \tau_{\text{BCOV}}(H_\infty, \omega) \\
&\quad - \frac{1}{12d} \int_{H_\infty} c_1(TH_\infty, g^{TH_\infty}) \log \left| w_1^{m_1} (dw_0)^{-m_1-m_2-2d} (dw_1)^d \right|^2 \right) .
\end{align*}$$

(3.25)
By (3.11), (3.15), (3.18) and (3.25), we have

\[
\tau_d(CP^2, \gamma_{m_1, m_2}) = \tau_{BCOV}(CP^2, \omega) - \frac{1}{12} \int_{CP^2} c_2(TCP^2, g^{TCP^2}) \log |dz_1 \wedge dz_2|^2 \\
- \frac{1}{12} \frac{1}{d} \int_{CP^2} c_2(TCP^2, g^{TCP^2}) \left( m_1 \log |z_1|^2 + m_2 \log |z_2|^2 \right) \\
- \frac{m_1}{m_1 + d} \left( \tau(CP^1) - \frac{1}{12} \int_{H_1} c_1(TH_1, g^{TH_1}) \log |dz_1|^2 \right) \\
- \frac{m_2}{m_2 + d} \left( \tau(CP^1) - \frac{1}{12} \int_{H_2} c_1(TH_2, g^{TH_2}) \log |dz_2|^2 \right) \\
- \frac{m_1 + m_2 + 3d}{m_1 + m_2 + 2d} \left( \tau(CP^1) \right) \\
+ \frac{1}{12} \frac{m_1 + m_2 + 2d}{d} \int_{H_\infty} c_1(TH_\infty, g^{TH_\infty}) \log |dw_0|^2 \right).
\]

(3.26)

Similarly to (3.18), we have

\[
\int_{CP^2} c_2(TCP^2, g^{TCP^2}) \log |z_1|^2 = \int_{CP^2} c_2(TCP^2, g^{TCP^2}) \log |z_2|^2 = 0.
\]

(3.27)

On the other hand, by (3.23), we have

\[
\int_{H_1} c_1(TH_1, g^{TH_1}) \log |dz_1|^2 = \int_{H_2} c_1(TH_2, g^{TH_2}) \log |dz_2|^2 = 0.
\]

(3.28)

From (3.26)-(3.28), we obtain (3.19). This completes the proof.

\[\square\]

3.3. Projective bundle. Let $Y$ be a compact Kähler manifold. Let $N$ be a holomorphic vector bundle of rank $r$ over $Y$. Set

\[
X = \mathbb{P}(N \oplus 1).
\]

(3.29)

Let $\mathcal{N}$ be the total space of $N$. We have $X = \mathcal{N} \cup \mathbb{P}(N)$.

Let $s \in \{0, \ldots, r\}$. Let $(L_j)_{j=1,\ldots,s}$ be holomorphic line bundles over $Y$. We assume that there is a surjective map

\[
N \rightarrow L_1 \oplus \cdots \oplus L_s.
\]

(3.30)

Let $N^*$ be the dual of $N$. Taking the dual of (3.30), we get

\[
L_1^{-1} \oplus \cdots \oplus L_s^{-1} \hookrightarrow N^*.
\]

(3.31)

Let $m_1, \ldots, m_s$ be positive integers. Let $d \in \mathbb{N}\setminus\{0\}$. Let

\[
\gamma_Y \in \mathcal{M}(Y, K_Y^d \otimes (\det N^*)^d \otimes L_1^{-m_1} \otimes \cdots \otimes L_s^{-m_s})
\]

be an invertible element. We assume that

- $\text{div}(\gamma_Y)$ is of simple normal crossing support;
- $\text{div}(\gamma_Y)$ does not possess component of multiplicity $-d$. 

We denote \( m = m_1 + \cdots + m_s \). Let \( S^m N^* \) be the \( m \)-th symmetric tensor power of \( N^* \). By (3.31) and (3.32), we have

\[
\gamma_Y \in \mathcal{M}(Y, K_Y^d \otimes (\det N^*)^d \otimes S^m N^*) .
\]

Let \( \pi : X = \mathbb{P}(N \oplus 1) \to Y \) be the canonical projection. We have

\[
(3.34) \quad K_X|_\mathcal{N} = \pi^*(K_Y \otimes \det N^*) .
\]

We may view a section of \( S^m N^* \) as a function on \( \mathcal{N} \). By (3.33) and (3.34), \( \gamma_Y \) may be viewed as an element of \( \mathcal{M}(\mathcal{N}, K_\mathcal{N}^d) \). Let \( \gamma_X \in \mathcal{M}(X, K_X^d) \) be such that \( \gamma_X|_\mathcal{N} = \gamma_Y \).

For \( j = 1, \ldots, s \), set

\[
N_j = \text{Ker}(N \to L_j) , \quad X_j = \mathbb{P}(N_j \oplus 1) \subseteq X , \quad X_\infty = \mathbb{P}(N) \subseteq X .
\]

We have

\[
(3.35) \quad N_j = \text{Ker}(N \to L_j) , \quad X_j = \mathbb{P}(N_j \oplus 1) \subseteq X , \quad X_\infty = \mathbb{P}(N) \subseteq X .
\]

Hence \( (X, \gamma_X) \) is a \( d \)-Calabi–Yau pair.

Let \( Z \) be the fiber of \( \pi : X \to Y \). Let \( U \subseteq Y \) be a small open subset. We fix an identification \( \pi^{-1}(U) = U \times Z \) such that there exist \( \gamma_U \in \mathcal{M}(U, K_U^d) \) and \( \gamma_Z \in \mathcal{M}(Z, K_Z^d) \) satisfying

\[
(3.37) \quad \gamma_X|_{\pi^{-1}(U)} = \text{pr}_1^*(\gamma_U) \otimes \text{pr}_2^*(\gamma_Z) .
\]

Then \( (Z, \gamma_Z) \) is a \( d \)-Calabi–Yau pair.

The following theorem was proved by Zhang [61, Theorem 3.6]

**Theorem 3.5.** The following identity holds,

\[
(3.38) \quad \tau_d(X, \gamma_X) = \chi_d(Y, \gamma_Y) \tau_d(Z, \gamma_Z) .
\]

**3.4. Blow-up.** Let \( (X, \gamma) \) be a \( d \)-Calabi–Yau pair. We denote

\[
(3.39) \quad \text{div}(\gamma) = D = \sum_{j=1}^t m_j D_j .
\]

Let \( Y \subseteq X \) be a connected complex submanifold intersecting \( D_1, \ldots, D_t \) transversally. Assume that for \( j \in \{1, \ldots, t\} \) satisfying \( Y \subseteq D_j \), we have \( m_j > 0 \). Let \( r \) be the codimension of \( Y \subseteq X \). Let \( s \) be the number of \( D_j \) containing \( Y \). We have \( s \leq r \).

Without loss of generality, we assume that

\[
(3.40) \quad Y \subseteq D_j \text{ for } j = 1, \ldots, s ; \quad Y \not\subseteq D_j \text{ for } j = s + 1, \ldots, t .
\]

Let \( f : X' \to X \) be the blow-up along \( Y \). Let \( D'_j \subseteq X' \) be the strict transformation of \( D_j \subseteq X \). Set \( E = f^{-1}(Y) \). We denote \( D' = \text{div}(f^*\gamma) \). We denote

\[
(3.41) \quad m_0 = m_1 + \cdots + m_s + rd - d .
\]

We have

\[
(3.42) \quad D' = m_0 E + \sum_{j=1}^t m_j D'_j .
\]

Hence \( (X', f^*\gamma) \) is a \( d \)-Calabi-Yau pair.
Set
\begin{equation}
D_Y = \sum_{j=1}^{l} m_j (D_j \cap Y), \quad D_E = \sum_{j=1}^{l} m_j (D'_j \cap E),
\end{equation}
which are divisors with simple normal crossing support.

We identify \(\mathbb{CP}^r\) with \(\mathbb{C}^r + \mathbb{CP}^{r-1}\). Let \((z_1, \cdots, z_r) \in \mathbb{C}^r\) be the coordinates. Let \(\gamma_{r, m_1, \cdots, m_s} \in \mathcal{M}(\mathbb{CP}^r, K^d_{\mathbb{CP}^r})\) be such that
\begin{equation}
\gamma_{r, m_1, \cdots, m_s} \mid_{\mathbb{C}^r} = (dz_1 \wedge \cdots \wedge dz_r)^d \prod_{j=1}^{s} z_j^{m_j}.
\end{equation}
Then \((\mathbb{CP}^r, \gamma_{r, m_1, \cdots, m_s})\) is a \(d\)-Calabi-Yau pair.

The following blow-up formula was proved by Zhang [61, Theorem 0.5].

**Theorem 3.6.** The following identities hold,
\begin{equation}
\tau_d(X', f^* \gamma) - \tau_d(X, \gamma)
= \chi_d(E, D_E) \tau_d(\mathbb{CP}^1, \gamma_{1,m_0}) - \chi_d(Y, D_Y) \tau_d(\mathbb{CP}^r, \gamma_{r, m_1, \cdots, m_s}).
\end{equation}

**Remark 3.7.** Keep the notation in Theorem 3.6. Let \(g : \text{Bl}_0 \mathbb{CP}^r \to \mathbb{CP}^r\) be the blow-up along \(0 \in \mathbb{C}^r \subseteq \mathbb{CP}^r\). Since \(\text{Bl}_0 \mathbb{CP}^r\) is a \(\mathbb{CP}^1\)-bundle over \(\mathbb{CP}^{r-1}\), by Theorem 3.5,
\begin{equation}
\tau_d(\text{Bl}_0 \mathbb{CP}^r, g^* \gamma_{m_1, \cdots, m_s}) = \chi_d(\mathbb{CP}^{r-1}, D_{m_1, \cdots, m_s}) \tau_d(\mathbb{CP}^1, \gamma_{m_0}).
\end{equation}

Note that \(\chi_d(E, D_E) = \chi_d(Y, D_Y) \chi_d(\mathbb{CP}^{r-1}, D_{m_1, \cdots, m_s})\), we could reinterpret Theorem 3.6 as follows,
\begin{equation}
\tau_d(X', f^* \gamma_X) - \tau_d(X, \gamma_X)
= \chi_d(Y, D_Y) \left(\tau_d(\text{Bl}_0 \mathbb{CP}^r, g^* \gamma_{m_1, \cdots, m_s}) - \tau_d(\mathbb{CP}^r, \gamma_{m_1, \cdots, m_s})\right).
\end{equation}

**4. Motivic integration and BCOV invariants**

In this section, we use the theory of motivic integration to explain our key construction, namely, the BCOV invariant for pairs \(\tau(X, \gamma)\).

**4.1. Motivic integration.** We consider an \(n\)-dimensional complex algebraic variety \(X\) and an effective divisor with simple normal crossing support \(D = \sum_{j=1}^{l} m_j D_j\) on \(X\). Denote by \(\mathcal{L}_\infty(X)\) the space of formal arcs in \(X\), that is, the projective limit of jet schemes \(\mathcal{L}_n(X) := X (\mathbb{C}[t]/(t^{n+1}))\) (see [29, §1]). Let
\begin{equation}
\text{ord}_D : \mathcal{L}_\infty(X) \to \mathbb{N} \cup \{+\infty\}
\end{equation}
be the function sending a formal arc to its intersection number with the divisor \(D\).

Let \(\text{Var}\) be the category of complex algebraic varieties. The Grothendieck group of complex algebraic varieties, denoted by \(K_0(\text{Var})\), is the free abelian group generated by the isomorphism classes of objects in \(\text{Var}\), modulo the scissor relation:
\begin{equation}
[X] = [Y] + [X \setminus Y] \quad \text{for any } X \text{ and any closed subvariety } Y \subseteq X.
\end{equation}

\(K_0(\text{Var})\) is endowed with a natural ring structure given by the fiber product.

Let \(\mathbb{L}\) be the class of the affine line. We denote \(\mathcal{M} = K_0(\text{Var})[\mathbb{L}^{-1}]\), the localization of \(K_0(\text{Var})\) with respect to the multiplicative system \(\{\mathbb{L}^k\}_{k \in \mathbb{N}}\). For any integer \(i\), let
$F^i\mathcal{M} \subseteq \mathcal{M}$ be the subgroup generated by elements of the form $\mathbb{L}^{-m}[Y]$ with $m - \dim(Y) \geq i$. Then $F^*$ is a filtration on $\mathcal{M}$. Let $\widehat{\mathcal{M}}$ be the completion of $\mathcal{M}$ with respect to $F^*$. The motivic Igusa zeta function\textsuperscript{3} is by definition

\begin{equation}
Z(X, D; T) := \int_{L_\infty(X)} T^{\text{ord}_D} d\mu \in \widehat{\mathcal{M}}[[T]],
\end{equation}

where $\mu$ is the motivic measure constructed by Kontsevich [45] and Denef–Loeser [29, Definition-Proposition 3.2].

The following theorem gives a formula for $Z(X, D; T)$, see [19, Theorem 3.3.4].

**Theorem 4.1.** The following identity holds,

\begin{equation}
Z(X, D; T) = \sum_{J \subseteq \{1, \ldots, l\}} \mathbb{L}^{[J] - n} \left( \prod_{j \in J} \frac{1 - T^{-m_j}}{1 - T^{-m_j} - 1} \right) [D_J],
\end{equation}

where $D_J = \bigcap_{j \in J} D_j$ with the convention that $D_\emptyset = X$.

Let $d$ be a positive integer. We define

\begin{equation}
F_d(X, D) := Z(X, D; \mathbb{L}^{-1/d}) = \sum_{m=0}^{\infty} \mu\left( \text{ord}_D^{-1}(m) \right) \mathbb{L}^{-m/d} \in \widehat{\mathcal{M}}[[\mathbb{L}^{1/d}]].
\end{equation}

By (4.4), we have

\begin{equation}
F_d(X, D) = \sum_{J \subseteq \{1, \ldots, l\}} \mathbb{L}^{[J] - n} \left( \prod_{j \in J} \frac{1 - \mathbb{L}^{m_j/d}}{1 - \mathbb{L}^{m_j/d} - 1} \right) [D_J].
\end{equation}

An equivalent form of (4.6) when $d = 1$ is in Craw [26, Theorem 1.1].

Now we state the formula of change of variables, due to Kontsevich [45] and Denef–Loeser [30, Theorem 1.16]), in the following form taken from Craw [26, Theorem 2.19] (when $d = 1$).

**Theorem 4.2.** Let $X$ be a projective complex manifold. Let $f : X' \to X$ be the blow-up along a smooth center. Let $K_{X'/X}$ be the relative canonical divisor. Let $d$ be a positive integer. Let $D$ be an effective divisor on $X$ such that both $D$ and $f^*(D) + dK_{X'/X}$ are of simple normal crossing support. We have

\begin{equation}
F_d(X, D) = F_d(X', f^*D + dK_{X'/X}).
\end{equation}

### 4.2 From motivic integration to BCOV invariant.

Let $X$ be a smooth projective complex variety. Let $\gamma$ be a $d$-canonical form on $X$ such that $D = \text{div}(\gamma)$ satisfies the condition ($\ast_d$) in Definition 2.4. Hence $(X, \gamma)$ is a $d$-Calabi–Yau pair in the sense of Definition 3.1.

Recall that the Hodge realization is the ring homomorphism

\begin{equation}
\chi_{\text{Hdg}} : K_0(\text{Var}_C) \to K_0(\text{HS})
\end{equation}

that sends the class of a smooth projective variety $X$ to the class of its cohomology $H^*(X, \mathbb{Z})$ endowed with Hodge structure. It is easy to see that $\chi_{\text{Hdg}}(\mathbb{L}) = Z(-1)$ is the

\textsuperscript{3}It is usually denoted by $Z(X, \mathcal{I}_D; T)$, where $\mathcal{I}_D = \mathcal{O}_X(-D)$ is the ideal sheaf of $D$. 
Lefschetz Hodge structure, which we will denote by $L$ in the sequel. Therefore, for a Hodge structure $H^\bullet$ and $s \in \mathbb{Z}$, $L^s H^\bullet$ is the Tate twist $H^\bullet(-s)$, namely,

$$L^s H^k \mathbb{Z} = H^k - 2s \mathbb{Z}, \quad L^s H^{p,q}_C = H^{p-s,q-s}_C.$$

For a polynomial $f(x) = a_0 + a_1 x + \cdots + a_m x^m \in \mathbb{Z}[x]$, we denote

$$f(L) H^\bullet = \sum_{s=0}^m (L^s H^\bullet)^{a_s}.$$

By (4.6), we have

$$\chi_{\text{Hdg}}(F_d(X, D) \mathbb{L}^{\frac{n}{2}}) = \sum_J L^{|J| - \frac{n}{2}} \left( \frac{1 - L^{m_j/d}}{1 + m_j/d - 1} \right)^{H^\bullet(D_J)}.$$

Mimicking (1.3) and (1.12), for a Hodge structure $H^\bullet$, we define

$$\eta(H^\bullet) = \bigotimes_k (\det H^k)^{(-1)^k}, \quad \lambda_{\text{dR}}(H^\bullet) = \bigotimes_k (\det H^k)^{(-1)^k}.$$

We are interested in applying $\lambda_{\text{dR}}$ to (4.11). First we remark that

$$\eta(L H^\bullet) = \eta(H^\bullet), \quad \lambda_{\text{dR}}(L H^\bullet) = \left( \eta(H^\bullet) \right)^2 \otimes \lambda_{\text{dR}}(H^\bullet).$$

Therefore, for any polynomial $f$, we have

$$\lambda_{\text{dR}}(f(L) H^\bullet) = \left( \eta(H^\bullet) \right)^{2f(1)} \otimes \left( \lambda_{\text{dR}}(H^\bullet) \right)^{f(1)}.$$

Let $w_d^J$ be as in (2.9). For

$$f(x) = x^{|J| - \frac{n}{2}} \prod_{j \in J} \frac{1 - x^{m_j/d}}{x^{1+m_j/d - 1}},$$

we have

$$\lambda_{\text{dR}}(f(L) H^\bullet) = \left( \eta(H^\bullet) \right)^{(|J| - n) w_d^J} \otimes \left( \lambda_{\text{dR}}(H^\bullet) \right)^{w_d^J}.$$

By (4.11) and (4.16), we have

$$\lambda_{\text{dR}}\left( \chi_{\text{Hdg}}(F_d(X, D) \mathbb{L}^{\frac{n}{2}}) \right) = \bigotimes_J \left( \lambda_{\text{dR}}(H^\bullet(D_J)) \right)^{w_d^J} \otimes \left( \eta(H^\bullet(D_J)) \right)^{(|J| - n) w_d^J}.$$

Observe that the BCOV invariant $\tau_d(X, D)$ (cf. Definition 3.2) is essentially the Quillen metric on $\bigotimes_J \left( \lambda_{\text{dR}}(H^\bullet(D_J)) \right)^{w_d^J}$. On the other hand, by Definition 1.1, the Quillen metric on $\eta(H^\bullet(D_J))$ gives rise to $\tau_{\text{top}}(D_J)$, which vanishes by (1.10). Therefore, our BCOV invariant is essentially the Quillen metric on the determinant line (4.17).
5. Birational BCOV invariants

**Definition 5.1.** For any $d$-Calabi–Yau pair $(X, \gamma)$, its birational BCOV invariant is

$$\tau_d^{\text{bir}}(X, \gamma) = \tau_d(X, \gamma) - \frac{1}{2} \tau(CP^1) \chi_d(X, \gamma)$$

(5.1)

$$+ \left( -\frac{1}{2} \tau(CP^2) + \frac{3}{4} \tau(CP^1) \right) \chi''_d(X, \gamma) ,$$

where $\chi'_d(X, \gamma)$ and $\chi''_d(X, \gamma)$ are as in Definition 2.4, applied to the invariants $\chi'$ and $\chi''$ in Example 2.2.

For a Calabi–Yau manifold $X$ and a $d$-canonical form $\gamma$ on $X$ such that $\int_X |\gamma|^1/d = (2\pi)^{\dim X}$, we have

$$\tau_d^{\text{bir}}(X, \gamma) = \tau(X) - \frac{1}{2} \tau(CP^1) \chi'(X) + \left( -\frac{1}{2} \tau(CP^2) + \frac{3}{4} \tau(CP^1) \right) \chi''(X) .$$

(5.2)

**Lemma 5.2.** Let $(X, \gamma_X)$, $(Y, \gamma_Y)$ and $(Z, \gamma_Z)$ be as in Theorem 3.5. Then

$$\tau_d^{\text{bir}}(X, \gamma_X) = \chi_d(Y, \gamma_Y) \tau_d^{\text{bir}}(Z, \gamma_Z) .$$

**Proof.** Since $\chi'$ and $\chi''$ are log-type localizable invariants (Examples 2.2), Proposition 2.7 yields $\chi'_d(X, \gamma_X) = \chi_d(Y, \gamma_Y) \chi'_d(Z, \gamma_Z)$ and $\chi''_d(X, \gamma_X) = \chi_d(Y, \gamma_Y) \chi''_d(Z, \gamma_Z)$. Combining them with Theorem 3.5 allows us to conclude. \qed

**Lemma 5.3.** Let $(X, \gamma_X)$, $(Y, \gamma_Y)$, $f : X' \to X$ and $m_0, \ldots, m_s \in \mathbb{Z}$, be as in Theorem 3.6. We have

$$\tau_d^{\text{bir}}(X', f^* \gamma_X) - \tau_d^{\text{bir}}(X, \gamma_X)$$

(5.4)

$$= \chi_d(Y, \gamma_Y) \left( \chi_d(CP^{r-1}, D_{m_1, \ldots, m_s}) \tau_d^{\text{bir}}(CP^1, \gamma_{m_0}) - \tau_d^{\text{bir}}(CP^r, \gamma_{m_1}, \ldots, m_s) \right) .$$

**Proof.** Similarly to the proof of Lemma 5.2, we use Theorem 3.6, Remark 3.7 and Proposition 2.8. \qed

**Theorem 5.4.** For any $m_1, \ldots, m_n \in \mathbb{N}$, we have

$$\tau_d^{\text{bir}}(CP^n, \gamma_{m_1}, \ldots, m_n) = 0 .$$

(5.5)

**Proof.** We have (see Example 2.2)

$$\chi(CP^1) = 2 , \quad \chi'(CP^1) = 2 , \quad \chi''(CP^1) = 0 ,$$

$$\chi(CP^2) = 3 , \quad \chi'(CP^2) = 6 , \quad \chi''(CP^2) = 2 .$$

(5.6)

By Definition 2.4 and (5.6), for any $m_1, m_2 \in \mathbb{N}$, we have

$$\chi''(CP^1, \gamma_{m_1}) = 0 , \quad \chi''(CP^2, \gamma_{m_1, m_2}) = 2 , \quad \chi'(CP^1, \gamma_{m_1}) = 2 ,$$

$$\chi'(CP^2, \gamma_{m_1, m_2}) = 6 - 2 \left( \frac{m_1}{m_1 + d} + \frac{m_2}{m_2 + d} + \frac{m_1 + m_2 + 3d}{m_1 + m_2 + 2d} \right) .$$

(5.7)

By Theorem 3.3, Theorem 3.4, Definition 5.1 and (5.7), we have $\tau_d^{\text{bir}}(CP^1, \gamma_{m_1}) = \tau_d^{\text{bir}}(CP^2, \gamma_{m_1, m_2}) = 0$. Hence (5.5) holds for $n \leq 2$. We proceed by induction. Let $r \geq 2$ be an integer. Assume that

$$\tau_d^{\text{bir}}(CP^n, \gamma_{m_1}, \ldots, m_n) = 0 \quad \text{for} \quad n \leq r .$$

(5.8)
Let \( i : \mathbb{C}P^1 \hookrightarrow \mathbb{C}P^{r+1} \) be the extension of \( \mathbb{C} \ni z \mapsto (z,0,\ldots,0) \in \mathbb{C}^{r+1} \). Let \( f : \text{Bl}_{\mathbb{C}P^1} \mathbb{C}P^{r+1} \rightarrow \mathbb{C}P^{r+1} \) be the blow-up along \( i(\mathbb{C}P^1) \). Then \( \text{Bl}_{\mathbb{C}P^1} \mathbb{C}P^{r+1} \) is a \( \mathbb{C}P^2 \)-bundle over \( \mathbb{C}P^{r-1} \). By Lemma 5.2 and (5.8), we have

\[
(5.9) \quad \tau_{d}^{\text{bir}}(\text{Bl}_{\mathbb{C}P^1} \mathbb{C}P^{r+1}, f^* \gamma_{m_1,\ldots,m_{r+1}}) = 0.
\]

By Lemma 5.3 and (5.8), we have

\[
(5.10) \quad \tau_{d}^{\text{bir}}(\text{Bl}_{\mathbb{C}P^1} \mathbb{C}P^{r+1}, f^* \gamma_{m_1,\ldots,m_{r+1}}) - \tau_{d}^{\text{bir}}(\mathbb{C}P^{r+1}, \gamma_{m_1,\ldots,m_{r+1}}) = 0.
\]

From (5.9) and (5.10), we obtain

\[
(5.11) \quad \tau_{d}^{\text{bir}}(\mathbb{C}P^n, \gamma_{m_1,\ldots,m_n}) = 0 \quad \text{for} \ n \leq r + 1.
\]

This completes the proof by induction. \( \square \)

**Theorem 5.5.** Let \((X, \gamma_X)\) and \(f : X' \rightarrow X\) be as in Theorem 3.6. Then

\[
(5.12) \quad \tau_{d}^{\text{bir}}(X', f^* \gamma_X) = \tau_{d}^{\text{bir}}(X, \gamma_X).
\]

**Proof.** This is a direct consequence of Lemma 5.3 and Theorem 5.4. \( \square \)

6. Extension to the singular cases

We extend the theory of BCOV invariants to Calabi–Yau varieties with mild singularities. In this section, \(X\) is a normal projective complex variety of dimension \(n\).

**6.1. Definitions and basic properties.** Recall that a variety \(X\) is called \(\mathbb{Q}\)-Gorenstein if the canonical divisor \(K_X\) is \(\mathbb{Q}\)-Cartier, i.e., there exists a positive integer \(d\) such that \(dK_X\) is a Cartier divisor. The minimal value of such \(d\) is called the index of \(X\).

**Definition 6.1** (Canonical and KLT singularities [44, Definition 2.34]). Let \(X\) be a \(\mathbb{Q}\)-Gorenstein variety and let \(f : X' \rightarrow X\) be a log-resolution, i.e., \(f\) is a resolution of singularities and the support of the exceptional divisor \(E = \bigcup_{j=1}^{l} E_j\) is simple normal crossing. Write the equality of \(\mathbb{Q}\)-divisors

\[
(6.1) \quad K_{X'/X} = \sum_{j=1}^{l} a_j E_j,
\]

where \(K_{X'/X}\) is the relative canonical divisor \(K_{X'} - \frac{1}{d} f^*(dK_X)\) for any positive integer \(d\) divisible by the index of \(X\), where \(K_{X'}\) satisfies \(f_\ast K_{X'} = K_X\). We say that \(X\) has canonical singularities if \(a_j \geq 0\) for all \(j\). Similarly, \(X\) is said to have Kawamata log terminal (KLT) singularities if \(a_j > -1\) for all \(j\). The coefficients \(a_j \in \mathbb{Q}\) are called discrepancy numbers. The definitions are independent of the log-resolution \(f\).

**Definition 6.2.** A canonical (resp. KLT) Calabi–Yau variety is a \(\mathbb{Q}\)-Gorenstein normal projective complex variety \(X\) with canonical (resp. KLT) singularities such that \(K_X \sim_\mathbb{Q} 0\), where \(\sim_\mathbb{Q}\) is the linear equivalence relation for \(\mathbb{Q}\)-divisors.

Let us record the following basic result.
Proposition 6.3 (Integrability of volume form [53, Thm. 2.1], [36, Prop. 1.17]). Let $X$ be an $n$-dimensional variety with KLT singularities. Let $d$ be a positive integer divisible by the index of $X$. Then for any $\gamma \in H^0(X, \mathcal{O}_X(dK_X))$, the integral

$$\int_{X_{\text{reg}}} |\gamma|^{1/d}$$

converges, where $X_{\text{reg}}$ is the regular part of $X$ and $|\gamma|^{1/d}$ is the unique positive volume form on $X$ whose $d$-th power equals to $i^{n^2} \gamma \wedge \overline{\gamma}$.

We extend the birational BCOV invariant studied in §5 to varieties with KLT singularities, equipped with a pluricanonical form or a pluricanonical effective divisor.

Definition 6.4. Let $X$ be an $n$-dimensional variety with KLT singularities. Let $d \in \mathbb{N}_{>0}$ divisible by the index of $X$. Let $D \in |dK_X|$. Let $f: X' \to X$ be a resolution of singularities such that $\widetilde{D} \cup E$ is of simple normal crossing support, where $\widetilde{D}$ is the strict transform of $D$ and $E$ is the exceptional divisor. For any $\gamma \in H^0(X, \mathcal{O}_X(dK_X))$ such that $D = \text{div}(\gamma)$, we define

$$\tau_d^{\text{bir}}(X, \gamma) := \tau_d^{\text{bir}}(X', f^*\gamma).$$

Here the right hand side is defined in Definition 5.1. Note that $X$ having KLT singularities implies that $(X', f^*\gamma)$ is indeed a $d$-Calabi–Yau pair (i.e. Condition ($\star_d$) is verified).

We also define

$$\tau_d^{\text{bir}}(X, D) := \tau_d^{\text{bir}}(X, \gamma) + \frac{\chi_d(X, D)}{12} \log \left( \frac{(2\pi)^{-n}}{\int_{X_{\text{reg}}} |\gamma|^{1/d}} \right).$$

Note that the integral on the right hand side converges by Proposition 6.3.

In the next two lemmas, we show that $\tau_d^{\text{bir}}(X, \gamma)$ and $\tau_d^{\text{bir}}(X, D)$ are well-defined.

Lemma 6.5. The quantity $\tau_d^{\text{bir}}(X, \gamma)$ is independent of the resolution $f$.

Proof. As any two resolutions are dominated by a third one, it suffices to show that for a further blow-up $g: X'' \to X'$ satisfying the same properties, we have

$$\tau_d^{\text{bir}}(X', f^*\gamma) = \tau_d^{\text{bir}}(X'', g^*f^*(\gamma)).$$

But this follows from Theorem 5.5. \hfill \Box

Lemma 6.6. For any $z \in \mathbb{C}^*$, the following identity holds,

$$\tau_d^{\text{bir}}(X, z\gamma) = \tau_d^{\text{bir}}(X, \gamma) - \frac{\chi_d(X, D)}{12} \log |z|^{2/d}.$$

Proof. This is a direct consequence of [61, Proposition 3.4]. \hfill \Box

In the sequel, we use the same notation as in §4.1.

Definition 6.7. Let $X$ be a variety with KLT singularities. In the situation of Definition 6.1, the Gorenstein volume of $X$ is by definition

$$\mu^{\text{Gor}}(X) := \sum_{J \subseteq \{1, \ldots, d\}} \|J\|^{-n} \left( \prod_{j \in J} \frac{1 - \|a_j\|}{\|a_j + 1\| - 1} \right) [E_J] \in \tilde{\mathcal{M}}.$$
In other words, for any \( d \in \mathbb{N}_{\geq 0} \) divisible by the index of \( X \), \( \mu^{\text{Gor}}(X) \) is equal to \( F_d(X', dK_{X'/X}) \) defined in (4.6). By Theorem 4.2, the definition is independent of the choice of \( d \) and the log-resolution \( X' \). Note that when \( X \) is smooth, \( \mu^{\text{Gor}}(X) = \mathbb{L}^{-n}[X] \).

Let \( P_t : K_0(\text{Var}_C) \to \mathbb{Z}[t] \) be the ring homomorphism sending a smooth projective variety to its Poincaré polynomial, which extends to a ring homomorphism \( P_t : \hat{\mathcal{M}} \to \mathbb{Z}[[t, t^{-1}]] \) (cf. [19, §3.4.7]).

**Definition 6.8.** Let \( X \) be an \( n \)-dimensional variety with KLT singularities. The **stringy Poincaré polynomial** of \( X \) is defined as
\[
P_t(X) := P_t(\mathbb{L}^n \mu^{\text{Gor}}(X)) .
\]
Following Batyrev [4], we define the **stringy Betti numbers** of \( X \) as the coefficients of \( P_t(X) \). The quantities \( \chi(X) \), \( \chi'(X) \) and \( \chi''(X) \) are defined by the same formulas (2.5)–(2.7) with Betti numbers replaced by stringy Betti numbers. If \( X \) admits a crepant resolution \( Y \), the stringy invariants of \( X \) equal to the corresponding invariants of \( Y \).

**Definition 6.9.** Let \( X \) be an \( n \)-dimensional KLT Calabi–Yau variety (Definition 6.2). We define the (stringy) BCOV invariant of \( X \) as
\[
\tau(X) := \tau^\text{bir}_d(X, \emptyset) + \frac{1}{2} \tau(\mathbb{C}P^1) \chi'(X) + \left( \frac{1}{2} \tau(\mathbb{C}P^2) - \frac{3}{4} \tau(\mathbb{C}P^1) \right) \chi''(X) ,
\]
where \( d \in \mathbb{N}_{\geq 0} \) is divisible by the index of \( X \) and such that \( |dK_X| \neq \emptyset \), \( \tau^\text{bir}_d(X, \emptyset) \) is defined in (6.4) (it is independent of \( d \) by [61, Proposition 3.3]), \( \chi'(X) \) and \( \chi''(X) \) are the stringy invariants introduced in Definition 6.8. By (5.2), we recover the BCOV invariant when \( X \) is smooth.

**Remark 6.10.** Quotient singularities form one of the most important instances of KLT singularities, see [44, Proposition 5.20]. In particular, (complex effective) orbifolds, or equivalently, \( V \)-manifolds in the sense of Satake [54, 55], are KLT. A compact Kähler orbifold \( X \) is called Calabi–Yau if \( c_1(X) = 0 \in H^2(X, \mathbb{R}) \). On one hand, thanks to the orbifold version of the Beauville–Bogomolov decomposition theorem, due to Campana [17] and Fujiki [37], Calabi–Yau orbifolds have torsion canonical divisor. Therefore Calabi–Yau orbifolds are special cases of KLT Calabi–Yau varieties in the sense of Definition 6.2, hence their BCOV invariants can be defined as in Definition 6.9. On the other hand, the Quillen metric can be extended to orbifolds (see Ma [48, §2]) and enjoys similar properties as in the smooth case (see Ma [48, 47]). Hence the definition of BCOV invariant (see Definition 3.2) can be directly extended to Calabi–Yau orbifolds. We plan to compare the two definitions in the future.

### 6.2. Curvature formula

We extend the curvature formula [61, Theorem 0.4] to locally trivial families (in the sense of Flenner–Kosarew [35, Page 627]) of KLT Calabi–Yau varieties.

**Definition 6.11.** Let \( S \) be a complex manifold and \( \mathcal{X} \) a complex space. Let \( \pi : \mathcal{X} \to S \) be a flat and proper morphism, viewed as a family of complex spaces \( (X_t := \pi^{-1}(t))_{t \in S} \). The family \( \pi \) is called **locally trivial** if for any \( t \in S \) and any \( x \in X_t \), there are analytic open neighborhoods \( \Delta \subset S \) of \( t \) and \( \mathcal{U} \subset \pi^{-1}(\Delta) \subset \mathcal{X} \) of \( x \) such that we have a \( \Delta \)-isomorphism \( (\mathcal{U} \cap X_t) \times \Delta \simeq \mathcal{U} \).
Locally trivial families admit (strong) simultaneous resolution.

**Lemma 6.12** (Simultaneous resolution [3, Lemma 4.6 and Remark 4.7]). Let \( \pi : X \to S \) be a locally trivial family. Then there is a proper bimeromorphic \( S \)-morphism \( Y \to X \), which is a composition of blow-ups along locally trivial centers which are smooth over \( S \) and disjoint from the smooth locus of \( \pi \), such that the composed map \( \pi' : Y \to S \) is a submersion and for any \( t \in S \), the map \( Y_t := (\pi')^{-1}(t) \to X_t \) is a log resolution.

In the sequel, a Hodge structure (resp. variation of Hodge structures) is a finite direct sum of pure polarizable \( \mathbb{Q} \)-Hodge structures (resp. variations of pure polarizable \( \mathbb{Q} \)-Hodge structures), possibly of different weights. Following [33, Proposition 2.8], [32, (5.6)] and [62, (0.6)], we make the following definition:

**Definition 6.13.** Let \( S \) be a complex manifold. Let \((\mathcal{H}, \mathcal{H}^*)\) be a variation of Hodge structures over \( S \), where \( \mathcal{H} = \mathcal{H} \otimes \mathcal{O}_S \) and \( F^* \) is a Hodge filtration on \( \mathcal{H} \). For any \( k \in \mathbb{Z} \), denote by \( \mathcal{H}^k \) the weight-\( k \) part of the variation. For any \( p, q \in \mathbb{Z} \), denote \( \mathcal{H}^{p,q} := \text{Gr}_k \mathcal{H}^{p+q} \), which we view as a holomorphic vector bundle over \( S \). The Hodge form of the variation is the following \((1,1)\)-form on \( S \):

\[
\omega_{\mathcal{H}} := \frac{1}{2} \sum_{p,q} (-1)^{p+q} (p - q) c_1(\mathcal{H}^{p,q}, g^{\mathcal{H}^{p,q}}) \in A^{1,1}(S). \tag{6.10}
\]

Here \( g^{\mathcal{H}^{p,q}} \) is a Hermitian metric on \( \mathcal{H}^{p,q} \) such that \( g^{\mathcal{H}^{p,q}}(u, u) = g^{\mathcal{H}^{p,q}}(\bar{v}, \bar{v}) \). One can show (cf. [62, Proposition 1.1]) that \( \omega_{\mathcal{H}} \) is independent of the Hermitian metrics \( g^{\mathcal{H}^{p,q}} \). Clearly, \( \omega \) is additive with respect to short exact sequences of variations of Hodge structures, hence it gives rise to a group homomorphism:

\[
\omega : K_0(\text{VHS}_S) \to A^{1,1}(S), \tag{6.11}
\]

where \( \text{VHS}_S \) is the category of variations of Hodge structures over \( S \).

On the other hand, the Hodge realization can be performed in the relative setting: given a complex variety \( S \), there is a group homomorphism

\[
\chi_{\text{Hdg}, S} : K_0(\text{Var}_S) \to K_0(\text{MHM}_S) \tag{6.12}
\]

\[
(\pi : X \to S) \mapsto R\pi^* Q X,
\]

where \( \text{MHM}_S \) is the category of mixed Hodge modules over \( S \). However, note that if we start with a smooth proper morphism \( \pi : X \to S \), then the image \( R\pi^* Q X \) lies in \( K_0(\text{VHS}_S) \), the subgroup generated by variations of Hodge structures over \( S \).

Now let \( \pi : X \to S \) be a locally trivial family of KLT Calabi–Yau varieties. The Gorenstein volume in Definition 6.7 can be extended as follows. Take a simultaneous resolution (see Lemma 6.12) \( f : X' \to X \) with simple normal crossing exceptional divisor \( E = \bigcup_{j=1}^l E_j \), which is locally trivial over \( S \). For any \( 1 \leq j \leq l \), let \( a_j \in \mathbb{Q}_{>0} \) be the discrepancy number of the resolution \( f \) along \( E_j \). Then define the relative Gorenstein volume

\[
\mu^{\text{Gor}}(X/S) := \sum_{J \subseteq \{1, \ldots, l\}} \left[ L/|J| \right]^{-n} \left( \prod_{j \in J} \frac{1 - L \cdot a_j}{L \cdot a_j + 1 - 1} \right) \left[ E_J/S \right] \in \overline{\text{M}}_S[L^{1/d}], \tag{6.13}
\]

where \( \overline{\text{M}}_S \) is the completion of \( K_0(\text{Var}_S)[L^{-1}] \) with respect to the dimension filtration. Similarly to Theorem 4.2, \( \mu^{\text{Gor}}(X/S) \) is independent of the resolution \( f \).
Taking the Hodge realization and denoting $L := Q_{S}(-1)$ the Lefschetz variation of Hodge structure over $S$, we get

$$\chi_{Hdg,S}(\mu^{\text{Gor}}(X/S)) = \sum_{J \subseteq \{1, \ldots, l\}} L_{J}^{n} \left( \prod_{j \in J} \frac{1 - L_{w_{j}}}{a_{j} + 1} \right) H^{*}(E_{J}/S) ,$$

where $H^{*}(E_{J}/S)$ denotes the variation of Hodge structures $R_{\pi_{J,*}}Q_{E_{J}} := \bigoplus_{k} R^{k} \pi_{J,*}Q_{E_{J}}$, where $\pi_{J} : E_{J} \rightarrow S$ is the natural projection.

**Definition 6.14.** Let $\pi : X \rightarrow S$ be as above. Its (stringy) Hodge form, denoted by $\omega_{Hdg,X/S}$, is the image of $\chi_{Hdg,S}(\mu^{\text{Gor}}(X/S))$ via (6.11).

**Lemma 6.15.** Notation is as before. Taking a simultaneous resolution $f : X' \rightarrow X$ as above, the Hodge form can be computed as

$$\omega_{Hdg,X/S} = \sum_{J \subseteq \{1, \ldots, l\}} \left( \prod_{j \in J} \frac{-a_{j}}{a_{j} + 1} \right) \omega_{H}(E_{J}/S) .$$

**Proof.** It suffices to apply the homomorphism (6.11) to the right hand side of (6.14), and use the fact that $\omega_{H} = \omega_{LH}$. \qed

**Definition 6.16.** Let $\pi : X \rightarrow S$ be as above and $d$ an integer divisible by the index of fibers. The Weil–Petersson form of $\pi : X \rightarrow S$, denoted by $\omega_{WP,X/S}$, is defined as follows: for any open subset $U \subseteq S$ and any nowhere vanishing section $\gamma \in H^{0}(U, \pi_{s}O(dK_{X/S}))$ viewed as holomorphic family $\{\gamma_{s}\}_{s \in U}$, we define

$$\omega_{WP,X/S}|_{U} = -\frac{\bar{\partial} \partial}{2\pi i} \log \int_{X_{\text{reg}}} |\gamma_{s}^{\gamma}|^{1/d} ,$$

where $\int_{X_{\text{reg}}} |\gamma_{s}^{\gamma}|^{1/d}$ is the function $s \mapsto \int_{X_{\text{reg}}} |\gamma_{s}^{\gamma}|^{1/d}$ whose convergence is guaranteed by Proposition 6.3.

We are ready to prove Theorem C, which we state again for convenience.

**Theorem 6.17.** Let $\pi : X \rightarrow S$ be a flat family of KLT Calabi–Yau varieties. Assume that $\pi$ is locally trivial. Then the function $\tau(X/S) : S \ni t \mapsto \tau(X_{t})$ is smooth, where $\tau$ is the BCOV invariant in Definition 6.9. Moreover, we have

$$\frac{\bar{\partial} \partial}{2\pi i} \tau(X/S) = \omega_{Hdg,X/S} - \frac{\chi(X)}{12} \omega_{WP,X/S} ,$$

where $\chi(X)$ is the stringy Euler characteristic of a fiber of $\pi$, $\omega_{X/S}$ is the Hodge form in Definition 6.14, and $\omega_{WP,X/S}$ is the Weil–Petersson form in Definition 6.16.

**Proof.** The smoothness of $\tau_{X/S}$ comes from the existence of simultaneous resolutions.

Let $d \in \mathbb{N}_{>0}$ be such that $|dK_{X_{s}}| \neq \emptyset$. Notation being as before, we have

$$\frac{\bar{\partial} \partial}{2\pi i} \tau(X/S) = \frac{\bar{\partial} \partial}{2\pi i} \tau_{\text{bir}}(X/S, \emptyset)$$

$$= \frac{\bar{\partial} \partial}{2\pi i} \tau_{\text{bir}}(X'/S, \sum \{ d_{j}E_{j}/S \}) = \frac{\bar{\partial} \partial}{2\pi i} \tau_{d}(X'/S, \sum \{ d_{j}E_{j}/S \}) ,$$
Here the first and the third equalities come from the fact that $\tau_{d}^{\text{bir}} - \tau_{d}$ consists of topological invariants, which are constant in locally trivial families. The second equality comes from (6.3). By [61, Theorem 0.4],

$$\frac{\bar{\partial}\partial}{2\pi i} \tau_{d}(X'/S, \sum_{j} d_{a_{j}}E_{j}/S)$$

(6.19)

$$= \sum_{J \subseteq \{1, \ldots, l\}} \left( \prod_{j \in J} \frac{-a_{j}}{a_{j} + 1} \right) \omega_{H^{*}(E_{j}/S)} - \frac{1}{12} \chi_{d}(X', \sum_{j} d_{a_{j}}E_{j}) \omega_{WP,X'/S}.$$

By Lemma 6.15, we have

$$\sum_{J \subseteq \{1, \ldots, l\}} \left( \prod_{j \in J} \frac{-a_{j}}{a_{j} + 1} \right) \omega_{H^{*}(E_{j}/S)} = \omega_{\text{Hdg},X/S}.$$

(6.20)

Using Definition 6.16, we can show that

$$\omega_{WP,X'/S} = \omega_{WP,X/S}.$$

(6.21)

By the definition of the stringy Euler characteristic, we have

$$\chi_{d}(X', \sum_{j} d_{a_{j}}E_{j}) = \chi(X).$$

(6.22)

From (6.18)–(6.22), we obtain (6.17).

7. Birational invariance

In this section, we prove our main result Theorem B. Although it clearly contains Theorem A as the smooth case, we nevertheless choose to give first the proof in this special case to highlight the main idea:

Proof of Theorem A. Let $X$ and $X'$ be $n$-dimensional birationally isomorphic Calabi–Yau manifolds. By the weak factorization theorem of Abramovich, Karu, Matsuki, and Włodarczyk [1, Theorem 0.3.1] (see also [57]), there is a sequence of blow-ups and blow-downs along smooth centers:

$$X = X_{0} \dasharrow X_{1} \dasharrow \cdots \dasharrow X_{r-1} \dasharrow X_{r} = X',$$

(7.1)

such that for each $0 \leq i \leq r$, the unique canonical divisor $D_{i} \in |K_{X_{i}}|$ is of simple normal crossing support. For each $i$, let $\gamma_{i} \in H^{0}(X_{i}, \mathcal{O}_{X_{i}}(D_{i})) = H^{0}(X_{i}, \mathcal{O}_{X_{i}}(K_{X_{i}}))$ be such that $\int_{X_{i}} |\gamma_{i}|^{2} = (2\pi)^{n}$. By Theorem 5.5 and [61, Proposition 3.4], we have

$$\tau_{1}^{\text{bir}}(X_{i}, \gamma_{i}) = \tau_{1}^{\text{bir}}(X_{i+1}, \gamma_{i+1})$$

(7.2)

for all $i$. Hence

$$\tau_{1}^{\text{bir}}(X, \gamma_{0}) = \tau_{1}^{\text{bir}}(X', \gamma_{r}).$$

Combining this with (5.2), we see that in order to prove $\tau(X) = \tau(X')$, it is enough to show that $\chi'(X) = \chi'(X')$ and $\chi''(X) = \chi''(X')$. However, $\chi'()$ and $\chi''()$, defined in (2.6) and (2.7) respectively, are certain linear combinations of Betti numbers, hence are birational invariant for Calabi–Yau manifolds by Batyrev [5].

Now let us proceed to the proof in the general case.
Proof of Theorem B. Recall that $\mu_{\text{Gor}}(\cdot)$ was defined in Definition 6.7. By a result of Kontsevich [45] and Yasuda [58, Proposition 1.2], which extends a result of Batyrev [5], we have $\mu_{\text{Gor}}(X) = \mu_{\text{Gor}}(X')$. Then, by Definition 6.8, we have

$$
(7.3) \quad \chi'(X) = \chi'(X'), \quad \chi''(X) = \chi''(X').
$$

Let $f : \widetilde{X} \to X$ and $f' : \widetilde{X}' \to X'$ be log-resolutions. Let $d \in \mathbb{N}_{>0}$ be such that $dK_X \sim 0$ and $dK_{X'} \sim 0$ as Cartier divisors. Note that the hypothesis that $X$ and $X'$ have canonical singularities implies that any smooth birational model of $X$ and $X'$ admits a unique $d$-canonical divisor.

By Abramovich–Temkin [2, Theorem 1.2.1 and §1.6], there is a sequence of blow-ups and blow-downs along smooth centers:

$$
(7.4) \quad \widetilde{X} = X_0 \dashrightarrow X_1 \dashrightarrow \cdots \dashrightarrow X_{r-1} \dashrightarrow X_r = \widetilde{X}',
$$

such that for each $0 \leq i \leq r$, the (unique) $d$-canonical divisor $D_i \in |dK_{X_i}|$ is of simple normal crossing support. For each $i$, let $\gamma_i \in H^0(X_i, \mathcal{O}_{X_i}(D_i))$ be such that $\int_{X_i} |\gamma_i^{-1/d}| = (2\pi)^n$. By Theorem 5.5, we have

$$
(7.5) \quad \tau_{i}^{\text{bir}}(X_i, \gamma_i) = \tau_{i+1}^{\text{bir}}(Y_i, \gamma_{i+1})
$$

for all $i$. Let $\gamma \in H^0(X, \mathcal{O}_X(dK_X))$ and $\gamma' \in H^0(X', \mathcal{O}_{X'}(dK_{X'}))$ be such that $\int_X |\gamma|^{1/d} = \int_{X'} |\gamma'|^{1/d} = (2\pi)^n$. By Definition 6.4 and [61, Proposition 3.4], we have

$$
(7.6) \quad \tau_{d}^{\text{bir}}(X, \emptyset) = \tau_{d}^{\text{bir}}(X, \gamma) = \tau_{d}^{\text{bir}}(X, \gamma_0),
$$

$$
\tau_{d}^{\text{bir}}(X', \emptyset) = \tau_{d}^{\text{bir}}(X', \gamma') = \tau_{d}^{\text{bir}}(X', \gamma_r).
$$

From Definition 6.9, (7.3), (7.5) and (7.6), we obtain $\tau(X) = \tau(X')$. \hfill \Box
